As far as our observation goes, and it has had an extensive range not only in Ceylon but on the Neilgherries and in British Sikhim, *C. succirubra* remains everywhere true to type, the variations in size and appearance of foliage being due to circumstances of age and locality, this plant flourishing in a zone of altitude extending from 2,000 feet or even lower to considerably over 6,000 feet. On the Neilgherries there are very fine trees at an elevation of 6,400 feet, and in British Sikhim we saw splendid trees at an altitude which (latitude also considered) might be considered more trying to the plant. From young succulent plants rhubarb, or cabbage-like leaves of enormous size (approaching if not exceeding 2' X 1½') can be gathered, and the coolies greatly value them as platters for their "*choru.*" At high altitudes or, as in Sikhim, in latitudes beyond the tropics, the leaves become smaller. But, big or little, they always present the same corrugated appearance, and we have never seen it stated that any special variation has been observed in the more distinctly botanical tests of the appearance of flowers and fruits. Of the common red bark there seems to be but one species and one variety or form, differences even in the quality of bark being due only to the principle generally recognized that the higher the altitude at which these as well as other alkaloid-yielding plants are grown, the richer they are in quality, if not also in quantity, of alkaloids. Unless, therefore, in what we believe to be the rare cases in which hybridisation has taken place (and *C. succirubra* seems to be more an active than a passive agent in such cases), the cultivator is not called on to exercise further care in the selection of the seed of the *C. succirubra* than that of seeing that the seeds were gathered from trees of mature age, and that they were well ripened before being gathered. These conditions premised, and the seeds speedily sown and properly treated, seedlings of one type can be calculated on, and the resulting trees and their quantity and quality of bark will differ only according to the soil, climate, and altitude in which they are grown, the age to which they are allowed to attain, and the processes by which the bark is harvested,—renewed bark being ever double, at least, the value of "natural." Curiously enough, at the commencement of the experiment in India, this tree was ranked first, even good above *C. calisaya* as a *quinine* yielder. This it becomes only when it is made to produce renewed bark, and even then the quantity of quinine in the bark is not to be compared with that in good calisayas or even crown barks (*C. officinalis*). It is as a yielder of cinchonidine (an alkaloid but slightly inferior to quinine in therapeutical value) that the red bark tree is valuable. Unfortunately the extraction of the alkaloids is rendered difficult to the chemist by the presence of a large amount of colouring principle and of intractable tannin to an extent which suggests the use of this bark by leather dressers, should its price go lower than, we apprehend, it ever will. It is for tonic and other decoctions that the natural bark of *C. succirubra* is therefore chiefly valued in Britain, and the reason why it ranked No. 1 in the price currents of 1860, when Mr. McIvor commenced his wonderfully successful experiments, was that so reckless had been the proceedings of the Andesian cascarilleros that the red bark trees, yielding anything like good marketable produce, had been practically exterminated in accessible forests. Some of our readers may remember a communication by the veteran quinologist, Howard, to the editor of this journal, describing the welcome which the druggists gave to large thick pieces of red bark from New Valley, Dikoya, and Nanuoya. Such pieces were valued not only for exhibition in druggists' windows, but so excellent were the appearance and quality of the first consignments of red bark from Ceylon, that Mr. Howard suspected it would in some cases be substituted for *C. calisaya*, the richest of the quinine yielding barks. In recent years the character of this bark, equally with that of *C. officinalis*, has suffered in the London market, from the large preparation of bark from prunings exported from Ceylon. From what we observed in a recent tour through Lower Dimbula, Dikoya, and Maskeliya, we suspect the balance will speedily be restored in favour of stem bark. Finer pieces of such bark, we believe, it would be impossible to shew than those we saw at Ythanside, regular in length, and almost uniform in thickness. The trees in this case were coppiced, and the stems. cut into lengths of 4ft., were placed on supporting posts to be barked. In this way, the work was better done and in less than one-half the time occupied when the strippers are allowed to assume their favourite squatting attitude. Ordinary pruning knives seemed to answer well in this case, but stripping knives, or spokes—shaves, of an improved form have been invented by Mr. W. R. Waller. As our journey extended into Maskeliya, however, we found thousands of plants of this species being uprooted, the hardness of the times, no doubt, necessitating a process, by which, judging from experience in the Sikhim gardens, one-third is added to the produce and that of a superior quality. Those who fear that the cultivation of cinchonas may be over-done and the market glutted within the next quinquennial or decennial period should take note of the extent to which at present cinchonas in Ceylon, especially the red barks, are being cut down or rooted up. This may lead to a temporary lowering of prices, but we submit that it clears the way for the large cultivation now going on.

II.

In the preceding article we speak of the red bark trees as occupying a zone of altitude extending from 2,000, or under, to 6,000 feet or over. We had Ceylon and Southern India in view, of course. In the account of the experiment tried on the Khasia hills, we find it stated that these plants grew freely from 4,800 feet (above which the cold was too much for them) down to 800 feet,—down, in fact, to the level of the plain of Assam which is but slightly elevated above sea-level. Here, as elsewhere, however, the trees refused to grow on perfectly level ground. We have no information as to the quality of the bark grown so low as 800 feet. The difference of latitude, however, and the effect of that difference, have to be taken into account. The influences of local aspect, shelter, &c., are so powerful, that we suppose no fixed formula can be adopted to shew the equivalents of altitude and latitude. But we can refer to a very interesting

SEVEN PRIZE MEDALS awarded to GOODALL'S HOUSEHOLD SPECIALITIES. A single trial solicited from those who have not yet tried these preparations.

Goodall's
Yorkshire Relish

THE most delicious sauce in the world; enriches hot joints, stews, chops, fish, &c.; with soup it is charming, blends admirably with all gravies; makes cold meat a luxury; makes the plainest viands palatable; the daintiest dishes more delicious; a great addition to cheese; every dish is improved by its addition; epicures pronounce it the best sauce; beware of colourable imitations.

CAUTION.—It having come to our knowledge that an imitation of our celebrated Sauce, the Yorkshire Relish, is being palmed upon purchasers, we beg that they will insist upon having the only genuine Yorkshire Relish, bearing a label with the Trade Mark, a "Willow Pattern Plate," and our name, "GOODALL, BACKHOUSE and Co., LEEDS," with a protecting label over the stopper. We are sorry that respectable tradesmen should lend themselves to such an imposture for the sake of a little extra profit. Sold by Grocers, Oilmen, Chemists, &c., in bottles, 6d., 1s., and 2s. each.

Goodall's
Baking Powder

AWARDED Seven Prize Medals for superior quality. The best in the world. Defies comparison. Makes delicious puddings without eggs, pastry without butter, and beautiful light bread without yeast. One trial will convince the most sceptical of its superiority over others.

Sold by Grocers, Oilmen and Chemists, &c., in 1d. packets, 6d., 1s., 2s., and 5s. tins.

Goodall's
Custard Powder

FOR making delicious custards without eggs, in less time and at half the price. Delicious to plum pudding and jam tarts; delicious to stewed rice and all kinds of fruit; delicious to everything; delicious alone.

Give it a trial.—Sold in boxes, 6d. and 1s. each, by Grocers, Chemists, Italian Warehousemen, &c.

[illegible] Powder

ACKNOWLEDGED to be the only real substitute for eggs yet discovered; its action on Cakes, Puddings, &c., &c., resembles that of the egg in every particular, enriching them in colour and flavour, rendering them most wholesome and nutritious. One penny packet will go as far as four eggs! and one sixpenny tin as far as twenty-eight!

Sold everywhere, in 1d. Packets; 6d. and 1s. Tins.

Goodall's
Ginger Beer Powder

MAKES three gallons of the best Ginger Beer in the world for threepence. Invaluable for producing a delicious and invigorating beverage, possessing valuable medicinal properties, thereby rendering it the most wholesome and perfect beverage ever discovered for both winter and summer use, is easily made, and acknowledged the best and cheapest.

Sold in packets 3d. and 6d. each, by all Grocers, Chemists, and Italian Warehousemen, &c.

Goodall's
Quinine Wine

IS invaluable for indigestion, nervousness, gout, rheumatics, &c. A wineglassful twice or thrice a day will be found both grateful and efficacious in all cases in which a cordial tonic is required, far superior to sherry and bitters or bitter beer.

Sold by Chemists, Grocers, &c., at 2s. per bottle.

Goodall's
Mushroom Ketchup

CONFIDENTLY recommended to all true lovers of the Pure Mushroom. Prepared by a special Steam process, from the PURE JUICE, producing a FULL AND RICH FLAVOURED KETCHUP, unrivalled for its GREAT STRENGTH! PERFECT PURITY!! and UNSURPASSED FLAVOUR!!!

Sold in bottles at 6d., 1s., and 2s. each, by Grocers, Oilmen, and Italian Warehousemen all over the kingdom.

Goodall's
Brunswick Black

FOR Painting Stoves, Grates, Iron, Tin, &c. This invaluable composition is superior to any yet offered to the public, possessing great brilliancy, and thoroughly protecting the articles it is applied to.

Sold in bottles at 6d. and 1s. each by Grocers, Oilmen, Chemists, Italian Warehousemen, Ship Store Dealers, &c. Shippers and the Trade supplied by the Sole Proprietors,

GOODALL, BACKHOUSE, & CO., White Horse Street, Leeds, ENGLAND.

WITH THE NUMBER OF

THE INDIAN TEA GAZETTE,

OF WEDNESDAY, MAY 19th,

WAS COMMENCED A SERIAL STORY OF MUCH INTEREST AND INSTRUCTION

TO TEA PLANTERS,

ENTITLED

JACK RAYNSFORD—Planter,

A Story (Founded on Fact)

ILLUSTRATING

The Life, Experiences, and Adventures of a Tea Planter.

The Story will be continued throughout Volume VII., and will be separately paged from the rest of the *Tea Gazette*, so as to permit of its being afterwards bound up by itself.

The Work has been written by a TEA PLANTER of great experience, and will, it is believed, afford equal instruction with recreative reading. It deals, also, with the incidents and occasion of the late Naga Raid, and other Historical Record connected with Tea in India.

The Work is copyright, and can only be obtained by present or future Subscribers to the *Tea Gazette.*

Volume VII. (No. 73 of the Series) of the *Tea Gazette* commences with the No. of June the 2nd, but new Subscribers to that Volume will receive the first instalment of the Tale, published with the May 19 No.

The Half-yearly advance Subscription to the Indian Tea Gazette is Rs. 9.

10, HARE-STREET, CALCUTTA.

case which must largely govern that now referred to. In round numbers, the mean temperatures of Dimbula at 4,600 feet, and the Rungbee Valley in British Sikhim, 20° further north, are represented by the same figure, 65°. The difference of altitude between the two places is 5,268 feet, Rungbee being so much lower than Dimbula, and Dimbula so much higher, than Rungbee. For each parallel of latitude, therefore, there is a fall or a rise, as the case may be taken, of somewhat over 63 feet. The difference of latitude being as nearly as possible 20°, Dimbula being in 7°, and the Khasia Hills, like British Sikhim, in 27° we have to multiply 20 by 63 to get the equivalent in Ceylon, at 7 from the equator, of 800 feet in Assam, 27° north of the line. We, therefore, find that to get the same conditions of temperature as exist at the foot of the Khasia hills at 800 feet altitude we must not go lower in Ceylon than 2,060 feet, indeed, 2,100 would be nearer the mark. It would seem, therefore, that, even if *C. succirubra* not only grows readily but yields good bark in north-eastern India at 800 feet, we cannot expect equivalent results here below 2,000 feet. We have however admitted the great influence of local circumstances, and we should shrink from dogmatizing on such a subject in view of the extraordinary results yielded by Mr. Roberts's low-grown calisaya in Ceylon, knowing as we do, that this species in its native habitat flourishes rather above than below 5,000 feet. We believe that trees of *C. succirubra* have been grown and are growing in Ceylon considerably below 2,000 feet altitude. Have any analyses of such low-grown bark been made, and with what results? While on this subject of the effect of latitude in qualifying altitude, we cannot help noticing an astounding statement which occurs in Dr. King's report on the Ledgeriana plantations in Java. Those plantations are exactly the same number of degrees south of the equator which the district of Dimbula counts north of the line. The mean temperatures of two places so situated ought to be identical, or, allowing for some local influences, ought not certainly to differ by more than a couple of degrees. And if anything, Java, with active volcanoes, ought to shew the warmer temperature. But, if there be no mistake in Dr. King's report, the contrary is the case to such an extent that at 7° south in Java the climate at 5,100 feet above sea level is 10° colder than at the corresponding elevation under 7° north latitude in Ceylon! Dr. King's report states distinctly that "at Tjinirosan (6,100 feet above the sea) the mean average of the whole year is 53·5 Fahrenheit." Even if 53 should turn out to be a misprint for 58, which the other figures quoted do not render probable, a difference of temperature is shewn against Java as compared with Ceylon (latitude and altitude being similar) of 5°. Mr. Heelis' careful observations, extending over nine years, resulted in a mean temperature of a little over 65° at 4,600 in Dimbula. The equivalent at 5,100 feet would be 63. Our reasons for so affirming are these. Nuwara Eliya with an altitude of 6,150 feet has a mean temperature of 57°. We have thus a fall of 8° in 1,550 feet greater elevation, or less than 200 feet to every degree. But as the mean temperature of a damp grassy plain, such as Nuwara Eliya is (heat rapidly radiating into space and damp favouring frost), must be considerably lower than that of forestland a a similar elevation, we submit that the adoption of 63 as the mean temperature of Dimbula at 5,100 feet is fully justified, especially as Mr. Heelis' figure exceeded 65° by more decimals than Dr. King gives over 53°. Taking the report figures as correct, then, or even allowing that 53 may be a misprint for 58, why should an altitude of 5,100 in latitude 7° south in Java, be 10° or even 5 colder than a similar altitude, in the corresponding latitude north be in Ceylon? The greater mass of land in Java and Sumatra can scarcely account for the difference. Indeed the absence of volcanoes from Ceylon and its proximity to the great continent of India ought to counterbalance such conditions. Confessing our inability to solve the meteorological problem, we can now quite understand why the Dutch in Java are inclined to go lower with the cultivation of Ledgerianas.—*Ceylon Observer.*

CALISAYA LEDGERIANA IN UVA.

ONE of the most satisfactory experiments in the cultivation of Cinchona Ledgeriana we have yet heard of in Ceylon is that made on Cocagalla plantation in the Madulsima district. Two ounces of seed were obtained direct from Mr. Moens of the Java Gardens. This seed was sown in a nursery on 15th January 1879, and resulted in 40,000 fine healthy plants fit for putting out in the field. This is just the ratio laid down by the late Mr. McIvor—we may mention in passing, —namely 20,000 plants from each ounce of good seed. In the case of Cocagalla, the seedlings were transplanted in April, May, and June, and those plants again were put out in the clearing chiefly in November 1879. The manager now reports that the largest plant reaches 3½ feet in height from the ground, while a great many measure from 2½ feet to 1 foot, the largest and strongest being those originally put out in baskets. There can be no doubt that the Cocagalla clearing of this the finest description of cinchona is the most extensive as well as perhaps the most flourishing in the island. It remains to be seen how the trees will be affected at the critical period after the third year, but even at three years old such calisaya trees ought to be very valuable. We are assured that no difficulty whatever has hitherto been experienced in Madulsima in getting cinchonas to grow at any stage:—the seed in the nursery, the seedlings when pricked out, and the plants in the clearing, all seem equally to flourish. It will probably be found that the soil and climate of Uva are better suited to the growth of the Ledgeriana than those of any other district in the island, and, if possible, we must get Mr. Moens to pay a visit to Madulsima to pass an opinion on the fine clearing planted from his seed. But not only calisayas but crown bark trees flourish exceedingly well in the Uva districts. We lately mentioned officinalis trees which realized to their owners a *net* return of Rs. 5 each. Now we learn that trees grown on Craigellachie, Haputale have each yielded about 1¼lb. of bark which realized in London 7*s.* 10*d*, per lb. so that each tree was worth Rs. 7! There is every encouragement therefore to plant crown and yellow bark cinchonas throughout the principality. We should like to know if experiments have been made in planting in the Uva patanas, and with what results. We may mention that in Ramboda district the average height of officinalis trees, four years old, is 13 feet, while the finest tree measured is one 16 feet high and 14 inches in circumference a span from the ground; a tree three years old when rooted up, gave 17 ounces of dry bark including root, stem, and branch bark. All this experience is gained at between 4,500 and 5 500 feet elevation in a district where neither succirubra nor calisaya apparently succeed—at any rate so well as officinalis.

CINCHONA CALISAYA ON THE NEILGHERIES.—Mr. W. Forbes Laurie is good enough to send us (*Ceylon Observer*) the following memorandum on the results of his visit to the Neilgherries:—

"My visit to India has settled my mind very much against the growth of Calisayas. They may, and do, grow well when young, but the Neddiwuttum experience is that after they have attained a certain age, they die down from the top, and this too in soil far finer and more absorbent than anything of the kind I have ever seen in Ceylon, and where officinalis and succirubra not only do not die out, but are stripped of their bark every 18 months. Ceylon, however, holds the palm for quick growth. The finest succirubra I saw at 4,000 feet, measuring 55 feet in height. The finest officinalis 35 feet at 5,500 altitude—W.F.L."

Mr. Laurie must not attach too much importance to the Neddiwuttum experience in considering the cultivation of the calisaya in Ceylon. No doubt the finer kinds are more delicate and more difficult to cultivate successfully; but several experiments in Ceylon—in different districts and at different elevations—in Pussellawa, Dikoya, Maskeliya, and Upper Dimbula—are so far most encouraging. The gentleman who will be best able to speak with authority on this question, and on many others more or less allied, is Mr. Moens, of the Buitenzorg gardens, Java, and from a long letter received from him to-day, we are glad to learn that he will visit Ceylon and India during this year. His present intention is to start from Java about the middle of August, arrive at Ootacamund in September to be in time for the stripping on the Neilgherry Government plantations, visit British Sikhim in October-November, and take Ceylon on his way back, by which time he will be able to compare all the great fields of the cinchona planting enterprise in the East. We have little fear of Mr. Moens condemning the cultivations of Calisaya under certain conditions in Ceylon.

A NEW ENEMY TO PLANTERS.—The diseased seedling cinchona plant, enclosed by our Wynaad correspondent in his letter which we published last week, was forwarded by us to a scientific gentleman at Madras, who has kindly favoured us with the following as the result of a careful examination. The brown fainge-like substance growing on the cinchona leaflets is a curious fungus growth. The parasite is attached to the hairs of the cinchona, and consist of a net work of fibres and large numbers of spores, the equivalents of seeds in flowerless plants such as fungi. The fungus growth on each hair forms a clublike body, quite distinguishable by the naked eye. Owing to the large number of spore, the fungus, if once introduced into a nursery, would spread rapidly The cause of this disease, for so it may be called, is likely, excess of damp. The nursery in which the seedling grew is probably badly drained or too much in the shade. I do not think the fact that the site of the nursery is an old coolie burial ground, has any connection with the appearance of this enemy. I would say to the planter "look to your drainage and see that there is not to much shade."—*Madras Times.*

CINCHONA.—A good deal of Cinchona will be cut down and shipped during the present season, and be the means of returning a good income to the fortunate owners Already the export of the bark amounts to 377,182lbs., as compared with 132,307lbs. at the corresponding period of last year. *It is probable, however, that the cuttings of the present* year will leave very little old cinchona on the ground: by far the larger portion of that now growing is very young and not likely to yield bark for some time to come.—*Ceylon Times.*

TOBACCO.

EFFORTS have been made, but not with very great success, to cultivate tobacco of superior quality in parts of Arracan in British Burmah. The soil there is said to be as good as the soil in the Phillipine islands, but the Burmese are too conservative to adopt any new fangled schemes. It is thought that if the Government takes the entire scheme in hand, tobacco cultivation might be successfully carried on, and a decided improvement will be apparent in the quality of the leaf available.

CULTIVATION OF TOBACCO.

WE have already remarked that good tobacco soil is friable, it is absolutely necessary that the soil of the nursery be so; when time will allow of it, the soil should be broken up repeatedly, for some months before the seed is sown, to depth of at least eighteen inches. In districts, such as the Eastern, enjoying the North-East monsoon, this should be done not later than August, the seed sown after the burst of the monsoon and the p[illegible] into the field, while the soil is still saturated and moi[illegible]tion; unless the soil is rich in humus, the [illegible] with cattle manure, the soil of the nursery can not [illegible] in organic matter; having dug up the soil once, after a few [illegible] operation should be repeated, drains should be cut, and beds [illegible] twenty-five feet by four feet (such a bed will accomodate sufficient seed for an acre), and all weeds must be kept down until sowing time; this time having arrived the seed should be sown as cinchona seed is, that is to say the beds are dug up again to a depth of six inches, all stones removed, and the beds bevelled and surface mould sifted; to ensure equal distribution, and also to keep off insects mix the seed with twenty times its bulk of fine ashes, press down with a board, and cover over with a preparation of dried moss or grass, make the roofs to the beds so that no sun and ample light shall be admitted, and prick out the seedlings as soon as practically (the sooner the better) into prepared beds under cadjans. We have found the "transplanter" patented by Mr. Laurie, so effective that we should advise that each plant be pricked out in a two inch space and his smaller sized transplanter used in the planting out. The small seedlings will at first require watering at least twice a day with a very fine rose, when they are two to four weeks old they will require less care, and to harden them before putting out, should be watered less frequently. If a very fine and large[illegible] tobacco is grown, the plants will have to be not closer than 3 feet by 3 feet, or 4,840 plants to the acre; for the smaller leaf 3ft. by 2ft. will suffice, giving 7,260 to the acre.

It must be borne in mind that no crop repays care and trouble in the preparation of the soil as tobacco does. If the land is ploughed three months before it is planted, so much the better. The soil must be ridged before planting, and this is done best by the plough, *in* the ridge the plant might be one foot closer than the distance *between* the ridges. Tobacco is a very delicate plant and the greatest care must be used in planting out the seedlings. We can recommend no better system than the transplanter referred to already. The plants which should be put out in the evening require water at once and shade for the first few days. In dry weather and poor soil, water them twice every day until the plants have recovered transplanting, after which, little or no water will be required unless the soil is very poor and the weather very dry. After having rooted, the plants grow rapidly, when they have attained, a height of 9 inches, they should be dug round and the soil, washed into the furrows, returned round the stems; unless the soil is very rich, saltpetre should be applied in solution, with a watering pot, a small depression having been made round each plant to retain the manure; the soil must never be allowed to crust but must be constantly hoed up; insects must be carefully looked for and destroyed.

When the flower buds appear they must be broken off, and with them the upper and lower leaves of the plant. This process will force out suckers which must also be carefully removed or otherwise the size of the leaf will be affected; in going through the lines (holing, weeding, suckering, &c.,) great care must be taken not to tear the leaves, as they are valueless if torn. In about three months after planting, the marbled appearance and yellowish colour of the leaf will denote that it is matured and ready for harvesting.

We shall conclude our remarks upon this product by describing the processes observed in preparing the leaf for the market.—*Ceylon Times.*

THE PREPARATION OF TOBACCO.

WE have treated of the selection and of the planting of tobacco, and it remains for us to describe the best method of preparing the leaf.

The leaf having matured, it is only necessary to cut down the whole plant with a long knife (wetta-catty) close to the ground. This can be done only in perfectly fine weather, and when the morning dew is upon the plant. A frame-work of posts and horizontals should be fixed up under any clump of shade-giving trees, and the plants tied together by plaintain fibre in pairs, and gently placed across the bamboos, which are in turn placed on the frame work, so that the pendant plants do not touch the ground; in placing the plants on the bamboos it is well to see that they are not pressed together; the frame-work should be large enough to accommodate one day's cutting; the plants should be left there until they are withered which operation will probably take one day; care must be observed during the process that the leaves are not allowed to dry too quickly or they will become shrivelled and remain green. The withering being done and the leaves having acquired an old-rag-like feeling, the bamboos, with the plants hanging upon them, are carried to the drying shed. Before we can state the drying process, it is necessary to describe the dryingshed; we suppose that on each half acre plot of tobacco there should be built a shed 30 × 20 feet, but as the most temporary building will suffice, this need not prove a serious drawback, the walls of the shed should be 17 feet high roofed with cadjan, and having shutters in three tiers one above the other, and opposite each other, so as to regulate the current of air through the building; flush with the window heads of each tier should be erected frames to accommodate the bamboos upon which the withered plants hang. When there is a hot breeze blowing, the windows must be closed so as to avoid the danger of too rapidly drying. The plants should remain on the lower tier "close hung" until the leaves have turned yellow, which will be between six to ten days, they are next hung upon the upper tier, the windows opened and the plants "less hung," so that the air may circulate well around them until the light yellow has deepened in to golden or light brown. When at this stage all windows may be thrown open, and the plants may be hung close together on the highest tier; the evaporation from the leaf will be very little now. The drying and changing colour of the leaf generally begins from the margin to the mid-rib, when the mid-rib is entirely dried up and pliable, the tobacco is ready for the next process "stripping." As before said for stripping the leaf must be perfectly soft and elastic (a damp moist vault would make a good stripping-room). In the early mornings when the plants have absorbed some moisture, they should be first heaped to check evaporation, and stripped when the leaf can be best rolled and bent without breaking. The leaves, when stripped from the stem are at once "sorted." There should be four sorts thus, No. 1, large equal coloured and untorn; No. 2, large equal coloured and torn; No. 3, bottom leaves of inferior colour, and No. 4 refuse and shrivelled up leaves. Nos. 1 and 2 are used for wrapers. The leaves are next carefully smoothed down on a flat board, and tied up in "hands" from ten to twenty leaves each, according to the size of the leaf. Should the colour of these "hands" not be uniform, to give them a brown colour they may be "bulked" that is to say heaped, so as to encourage a slight fermentation, but in this operation great care must be taken to avoid over-heating and mouldiness. If the tobacco has been carefully dried, and is of a good variety, it may be smoked a week after curing. Many ingredients are used in the trade for improving colour, flavour, &c., but it is wiser, we think, to leave all this to the cigar manufacturer. It should be remembered that a good cigar depends much more upon the rolling and wrapping than is generally supposed, and many a good quality cigar is thrown away in disgust, although the tobacco is of the finest and the leaf has been carefully tended and cured.—*Ceylon Times.*

TOBACCO CULTURE IN AMERICA.

APROPOS of the cultivation of tobacco, we give the following notes on its cultivation in America.

1. Requires a light loamy soil.

2. Kinds of manure must be adapted to the quality of the tobacco as to its strength or mildness.

3. In temperate climates (*e. g.*, America), sown about beginning of March in a hot-bed, ready for transplanting by first week in Ma[illegible]

4. Is then "pricked" out singly, each plant [illegible] allowed [illegible] square feet of surface.

[5. That would be roundly in rows both ways 42 inches (3 feet 6 inches) apart. Four plants therefore form a square, of which they are the corners, having a side of 42 inches.]

6. Thus there will be 1,613 plants in an acre, no more if broad and vigorous leaves are required, such as will yield half a pound of prepared tobacco from each plant, on 800 lb. to the acre.

7. Transplantation requires great care, so as not to injure the delicate fibres of the young plant.

8. Carefully destroy all grubs, earthworms, and insects (which generally make a very virulent attack on the young tender plant), with lime, or sawdust for one month, when the plant is strong enough to take care of itself.

9. As it grows, every weed dies off beneath it, it occupies its space without competition.

10. A parasite in shape of a peculiar caterpillar will eat off the leaves, if you are not a vigilant morning and evening visitant to nip him in the bud!

11. Rapid growth must be discouraged and checked, a dozen leaves at the most are sufficient for each plant. Having developed this number, it must be "topped" off; and every flower-bed must be repeatedly removed to prevent it flowering, which would impair quality of leaf.

12. Early in September or later is the time for gathering. In hot climates at the time of maturity there is an odour of tobacco round about the plant.

13. The leaf when gathered is rich in juice, greenish as any autumnal leaf, and very brittle; the telling little story of rolling a cigar and smoking it from the fresh leaf is B. O S. H.

14. The leaves are then hung up in covered sheds or lofts admitting light and air freely on all sides, and there they remain for six or seven weeks until perfectly dry and withered.

15. A better plan, however, is to lay them in heaps, and give them a sweating for a week before suspension, the drying process will thus be more rapid, and flavour improved.

16. Thoroughly dried a moist, "juicy" day (as the Yankees call it) is chosen, the leaves are thrown in heaps on the floor covered with mats or blankets, and thus retained for the purpose of setting up the fermentation which results in the peculiar odour of tobacco, (this aroma being due solely to the process of fermentation, and not naturally belonging to the leaf as supposed).

17. The speed of this process will depend upon temperature—36 hours will sometimes suffice.

18. The fermentation must be stopped at attaining a precise degree of heat, which is ascertained by shoving in the hand, above or below that point, which practice makes easy of detection, the tobacco would be "foxy," and depreciated in the market.

19. The fermentation is stopped by uncovering, spreading out, and turning over the leaves.

20. Various modes of packing. In America the leaves are pressed by a powerful lever into hogsheads, which has an advantage in the effect of spreading the oil of the leaf uniformly through the mass.

THE

INDIAN AGRICULTURIST.

A MONTHLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. V.] CALCUTTA: MONDAY, 2ND AUGUST 1880. [No. 8.

NOTICE.

The INDIAN AGRICULTURIST *will be supplied to all Schools and Missionaries in India at half price.*

R. KNIGHT.
Proprietor.

Calcutta, 1st Feb. 1876.

CONTENTS:

NOTICE TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

CORRESPONDENCE.

MALIQUATA PEPPER.

TO THE EDITOR.

SIR,—I would feel obliged if you will kindly tell me which is the best market to sell Maliquata Pepper in; if there is much demand for it, and what price it fetches per lb.

C. SHODALAMOOTO PILLAY.

Sindoola, Ceylon, 5th July 1880.

NOTE.—We do not know the article; but if it is of general consumption, London cannot fail to be the proper market. If the consumption is purely local, then it ought to sell at the nearest sudder station to the centre of consumption.—ED., *I. A.*

"A NEW CEREAL."

TO THE EDITOR.

SIR,—In your issue of the 1st instant mention is made at page 195 of "a new cereal." Could you oblige by letting me know, if you are aware, where a small quantity can be had in India, for seed. I am anxious from the description given to make a trial of it in these parts.

W. A. POWELL.

Saharanpore, 22nd July 1880.

NOTE.—The cereal is new to America, but pretty well known here, being the *Sorghum Saccharatum*.—ED., *I. A.*

INFORMATION WANTED.

TO THE EDITOR.

SIR,—Can you oblige me with the following information through the medium of your widely circulated paper.

1. Is wood ash injurious to the cinchona plant? If so, why?
2. What manures are most suited for cinchona? and in what manner ought they to be applied?
3. Is it usual to find borer in cinchona?

My reason for asking the latter question is that a few days ago, while visiting an estate, my eye came across a tree looking very much withered up and in cutting it down to ascertain the reason, I found a red borer, similar to the coffee grub but longer; it was evidently this that was destroying the tree.

INQUIRER.

NOTE.—Our correspondent had better purchase the manual on cinchona cultivation published by Messrs. Higginbotham & Co., Madras, which will give him all the information he requires.—ED., *I. A.*

WOOD ASHES.

TO THE EDITOR.

SIR,—In reply to your correspondent STEPHEN HONLEY, I can state what my experience has been in the use of ashes from fuel burnt in an engine. I tried it on about fifty mango trees, one application to the roots every three months, for two years, and found that the trees were more healthy and free from vermin than those planted alongside. I have also used the same ashes as manure to some paddy land, and the crop was equally as good as the same kind of lands manured with stable litter. The value of wood ashes as manure is not in much esteem in these parts, probably from the facility with which horse and cattle manure can be purchased in Bangalore; but I agree with STEPHEN HONLEY that the belief that the ashes from wood burnt in the open air or on ordinary native hearths is in any way superior to the engine shed ashes, is a mistake—one thing is certain the latter does not kill trees.

A fine clump of trees close to the railway station here has grown up entirely fed on engine shed ashes; their appearance denotes vigor, and they are now between seven and eight years old.

THOS. T. LEONARD.

Bangalore, 7th July 1880.

THE GROUND NUT.

TO THE EDITOR.

SIR,—For the information of AFRICA, whose letter appears in your issue of the 1st instant, I send the following with reference to the planting of the ground nut (*Arachis hypogœa*).

The nuts being shelled, three, more or less, seeds are found, these are sown in the field prepared to receive them by two or three courses of ploughing. The seeds in these parts are dropped one by one in the furrow made by the plough, at intervals of about one foot, and the parallel plough furrows are about that distance apart, so that any four seeds ought to form the four points of a square of one foot. After two months, sometimes earlier, the plots must be weeded; the tendrils of the plant are thereby encouraged to shoot out luxuriantly.

The ground nut will yield a crop for three successive seasons, and on this account is considered to be very remunerative to the sower. In the second and third years, a sprinkling of manure and one course of ploughing, with the first fall of rain, serves to ensure the success of the crop.

A very good paper on the cultivation of the ground nut was issued by the Government of India, dated 2nd November 1877, and was republished, if I mistake not, in your much valued journal.

THOS. T. LEONARD.

Bangalore, 7th July 1880.

SHADE FOR COFFEE.

TO THE EDITOR.

SIR,—Will you or any of your correspondents be good enough to favor me with their views on the following subject, *viz.*, that of destroying superfluous shade trees? A portion of my estate was planted some ten or twelve years ago, with cuttings of various kinds of trees of the fig tribe as well as with jack seedlings. These all grew, and now throw such a dense shade upon the coffee, as greatly to interfere with its crop-producing power. I want to find some poison that, by inserting it in augur holes, will kill a portion of the trees, and which at the same time will not spread through the roots and poison the soil. I have tried girdling, but the trees seem little the worse for it, the sap apparently flowing through the pith, and roots being thrown down from above the incision. Felling destroys the coffee beneath, and necessitates the grubbing up of the stumps, a tedious and expensive process. Would salt, sulphate of copper, or sulphuric acid be likely to answer my purpose, and what quantity would be required for trees of about 9" diameter?

SHADE.

Coorg.

NOTE.—We are afraid our correspondent will have to prune his shade very heavily, or remove it altogether. His attempts at girdling have failed, because he has not cut deep enough. It may be noted that girdling in the early part of the rains does not take effect so speedily as if done at other seasons, for obvious reasons. Our correspondent must be joking when he speaks of killing only a portion of the tree by injecting strong poison into the trunk.—ED., *I.A.*

THE MANGO.

TO THE EDITOR.

SIR,—In answer to your Quilon correspondent's letter in your issue of the 1st instant, I would say, that instead of "notching the bark *on* two rings," it is stated that the notching was "*within* the two rings of chalkmark," each ring being 12 inches apart from the other, the circumference of the tree being 24 inches; and that, on this superficial area, 80 notches of about one to one-third of an inch were made. The rings of chalkmark merely serving as a sort of boundary beyond which there was no necessity to wound. I also stated that it was the *first time* that the tree was in bearing, and consequently did not state the largeness of the fruit, was the result of the process. I also stated that while another tree of the same age did bear, then, for the first time, all fell off, prematurely, notwithstanding the advantage it had of having a considerable amount of shelter about it, while the tree that was notched stood away by itself without the least shelter on any side.

I never heard any one complain that either fruit or vegetable lost in richness of flavour by being well manured and carefully attended to. How is it possible then that it can be so to fruit growing on trees that have neither water nor manure at any time? I would however, recommend the digging up of the soil of all fruit trees with a pickaxe, allow the clods to remain unbroken for a week or fortnight then manure with high or strong stuff, and run a stream of water on it. Continue the watering once a week, or a fortnight at most. Those that do so, will find that they will have ripe fruit long before those who neither manure nor water, the fruit meantime gaining in richness of flavour. I witnessed this as a fact for four years in Chittoor, 100 miles west of Madras. This station is about 30 miles N.-W. of Arcot, and 20 N. of Vellore—the stations that Dr. Short states the people were in the habit of suspending the heavy fruit, pumaloes, &c., &c. I believe the doctor states what he saw, still it is strange that in a station only 25 miles away, such a thing was not practised during the four years that I was in it. Nor had anyone any idea there that notching trees would prevent the fruit from falling off *prematurely*, and yet there were gentlemen such as Sir John D'Acre and Mr. Peters, the Collector; both of whom took a great interest in the cultivation of fruit, mangoes being called by their name to this day. Now though I did not state that notching increased the size of the fruit, still there cannot be the least doubt that when it serves to keep the sap up, and thereby prevents the fruit from falling from want of nourishment, it must as a matter of course enable the fruit to grow large from the full measure of nourishment it is able to supply it with. The first place where I saw the process, was in the hill ranges of the Ganjam district, by the hill men called "Cours." The Telegue people on the coast did not understand or practice it, though the mangoes from the wounded trees were not only the largest, but in reality superior to all the rest of the fruit in the district. I recollect seeing some graft trees that sent out all their main branches so low down, that left no main body to wound. In such instances operate on the main branches as low down as possible; this would answer the purpose, but when it can be done on the body of the tree, the labour and time taken to do so on four or five branches is saved.

OBSERVER.

15th July 1880.

"CHALKMARK" AND ROOT JACK.

TO THE EDITOR.

SIR,—The two lines of "chalkmark" drawn round the bark of the tree at the distance of 12" from each other, was intended to confine the wounding process within that limit. The circumference of the tree was 24," and the number of cuts was 80," on this surface within these two lines, each cut being from half to three-fourths of an inch in length, and not penetrating deeper than the bark. Take care to wound in a fresh place for three or four years, so as to give time for the thorough healing and filling up of the wounds, after which time the same place can safely undergo the same operation again.

"Live and learn" is a motto we ought all to abide by. I quote this with reference to the statement of PLANTER OF COONOOR, from whose statement I learn for the first time that the jack tree that yields fruit on the root is a distinct tree from all others.

I never saw more jack trees or fruit in any place than in Coongul, the Government Horse Stud, forty miles west of Bangalore, where business would take me from village to village throughout the year, and where the fruit would be heaped up in piles. Every individual on being asked, always assured me that the tree that bore at the root, was *not* of a different kind, but all were alike, and that bearing at the root depended on the age of the tree. While in Wynaad I used to go to the *courchers* (landed proprietors). One gave a jack from the root. There were several of the same age planted from the seed of the same fruit, but only a few had borne at the roots, up to that time; there were others that the man showed that were planted by his father, of which only one bore at the root, and other trees that the person planted when a young man, all from the seeds of the fruit of the same trees, but none of which had up to that time borne on the root.

In Bengal, a zemindar living at the N.-E. angle of the Vindian range of hills, gave the same information when giving me a fruit from the root of the tree. But since reading the statement of PLANTER, I have made fresh inquiries. Only one native gentleman agreed with PLANTER in stating positively that a tree in his garden yielded fruit at the root "for the first time," *i. e.*, that the tree bore at the root on the *first* occasion of its yielding. On a few questions being put to him, he asked for time to make further inquiries, to be certain, when it turned out that the tree had been bearing for years past, over trunk and branches, but that this was the first time it bore at the root! Now the question is, was the tree that PLANTER describes as having "borne on the root at the fifth year" a tree that sprang up direct from seed in the same place in which it now stands, or was it transplanted from the nursery? A mango tree does not bear fruit before the 12th or 14th year, if it has *not* been transplanted, while if, when in transplanting, you either break or intentionally cut the tap root, then the tree will bear within eight or nine years, "Nature as it were making an extraordinary effort to reproduce the specie."

Now if that tree of PLANTER's has been transplanted, and at that time had its tap root broken or injured, then this may account for its yielding on its root at such an early age. I do not claim to be infallible,

WINES, &c.

INTRODUCED BY

W. & A. GILBEY,

SPARKLING "BRUT SAUMUR" CHAMPAGNE

FROM

FRANCE.

SECOND SHIPMENT TO THIS COUNTRY.

Just landed ex S.S. "Merkara" and in splendid condition.

Early application necessary to prevent disappointment.

"CASTLE BRUT SAUMUR"

Is the produce of selected grapes grown in the extensive wine districts of Saumur, an invaluable sparkling wine to those who require wines free from all saccharine. It is strictly what is known as a "Brut" or "Natural" wine, that is to say, no saccharine has been added since the completion of the Fermentation.

Quarts, per dozen ...	... Rs.	28 0
Pints „ 2 „ ...	... „	30 0

Dr. Druitt writing in the *Medical Times and Gazette* of the 29th March 1879, states as follows :—

"Added to the practical experience of the last dozen years "during which I have known these wines, I may give "the following theoretical reasons for the superiority of "*Vin Brut* as a stimulant in many cases, more par- "ticularly *dyspeptic* and others where the consumption "of sugar should be avoided.

"*First.*—The Brut wine is STOUTER and MORE GENEROUS.

"*Second.*—It is more APPETITE-COMPELLING.

"*Thirdly.*—The extra degorgement and the absence of "dosage with sugar and brandy render Brut "Saumur less liable to disagree, while it meets "for INVALIDS A WANT THAT HAS LONG BEEN FELT "by the medical profession, but which perhaps pre- "viously has not been within general grasp (*viz.*) that of "a PURE SPARKLING and MODERATELY STIMULATING "BEVERAGE at a reasonable price. The man in perfect "health may drink which he likes best, without fear of "the small quantity of sugar in the ordinary wine, but "if he prefers a dryer wine, here it is."

The following also is the report of Dr. D. Waldie, F.C.S., after analysis :—

"The results of this (analysis) indicate that the Brut Saumur is a NATURAL WINE like other NATURAL UN "SACCHARTED or UNFORTIFIED WINES, the nature and "properties of the constituents of which have been "ascertained, so far as I can judge, from the analysis, "it is a GOOD WHOLESOME WINE, possessing the properties "belonging to the BEST NATURAL WINES, without the "peculiarities of certain kinds, objectionable in many "cases, such as the astringency of Clarets or the "excessive amount of alcohol, or sugar in others."

With the opinions of two such well-known authorities both in England and in India, we offer the above wine to our constituents and the public.

Also to hand ex "Merkara."

A TRIAL SHIPMENT OF

W. & A. GILBEY'S OLD TOM.

It is distilled from the best UNMALTED CORN and HIGHLY RECTIFIED at Messrs. Gilbey's Own Distillery. It possesses the delicate flavour of the Juniper.

Rs. 18 per dozen.

THE

CALCUTTA MUSICAL ESTABLISHMENT,

No. 13/1, Government-place, East.

(Late BURKINYOUNG & CO.)

FOUNDED, A.D. 1814.

Proprietor—CHARLES GOULD.

THE SMITH AMERICAN ORGAN,

Wholly new designs and effective combinations in Reed Organs.

THE American Organ has been, and still is, the most popular and valued instrument for Churches and Chapels. Immense numbers of them are used in public worship, and it has been found that no other Reed Organs have so much sustaining power joined with such melodious quality of tone.

Style No. 10, *Seven Stops.*

This Style is furnished with two complete sets of reeds of five Octaves. Each set is divided and has a separate stop, for the upper and lower half. The upper half of the first set of reeds is named Flute, and the lower half Principal. In the second set the upper half is named Dulciana, and the lower Diapason. The first set is an Octave higher in pitch than the second, so that the instrument has practically a compass of six Octaves. By having the sets divided, it will be seen that more effect can be produced. The remaining stops are Tremelo, Diapason Forte, and Principal Forte. [*Net Cash, Rs. 400.*

Style No. 16, *Ten Stops.*

This instrument has two and-a-half sets of reeds, and an Octave of Sub-bass. It has ten stops, *viz.*, Diapason, Dulciana, Flute, Principal Kulophon, Sub-bass, Tremelo, Principal Forte, Diapason Forte, and Octave Coupler. The last stop doubles the power of the Organ, and with the aid of the Sub-bass renders it a powerful and effective instrument for Churches and Halls; at the same time its power is not obtained at any sacrifice of delicacy, and it will be found a most desirable instrument for home use. [*Net Cash, Rs. 650.*

Style No. 20, *Nine Stops.*

This instrument has three complete sets of reeds. Two of the sets are like those in the preceding Styles, having the Principal and Forte Diapason and Dulciana stops. The third set is new and distinct in quality, the upper half is named "Aulodia" and the lower half "Fagotte." The tones of this set are unrivalled in clearness, smoothness, and tender beauty, and their effects in connection with the swell are surprising.

This Organ is one that will be approved by all persons of refined taste. [*Net Cash, Rs. 750.*

***N.B.*—The above prices are exclusive of packing charges.**

SELLERS' QUINQUININE

Entirely supersedes Quinine, at about one-third the price.

J. SELLERS, the inventor of the process for manufacturing this article, confidently recommends it for use in India and all districts where Quinine is employed.

It is the only reliable combination of the entire alkaloids of bark, and as a tonic and antiperiodic in the treatment of Ague Fevers, and Malarial diseases, it is superior to the Sulphate of Quinine.

It is used in several of our large Hospitals, and very extensively in private practice with the greatest satisfaction.

It resembles Quinine in appearance, and is given in the same doses as Quinine.

In an article on Cinchona and its alkaloids in the *British Medical Journal*, June 28th, 1879, the writer states:—"Sellers' Quinquinine and Howard's Quinine are equally good medicines. On this point I speak from careful observation, uninfluenced by chemical analysis, or by the statement of the vendors. Sellers' Quinquinine is similar in appearance to Howard's Quinine."

J. Sellers, the inventor and solemaker, cautions purchasers against worthless and spurious imitations which are being advertised. Every genuine package bears the label of J. Sellers, London. Sellers' Quinquinine should always be stated in orders.

Sold in 1 oz. bottles, 5s. 0d., and in 4 oz. bottles and 25 oz. tins at reduced rates.

SELLERS' MISTURA BISMUTHI COMP.,

(Registered), Stomachic and Anti-Dyspeptic, a perfect solution of Bismuth, miscible with water without precipitation, and is acknowledged to be the most useful, convenient, and efficacious preparation of Bismuth we possess; being often given with benefit when all other preparations of Bismuth have signally failed.

In cases of dyspepsia, pain after food, gastric irritation with sickness, nausea, especially due to pregnancy, and whenever there is general depression and lack of nervous energy, with loss of appetite or inability to assimilate the food, it is given with almost unfailing success. In those troublesome and difficult cases arising from sedentary habits, or excesses of any kind, so frequently met with in medical practice, it is a most reliable remedy. It is specially adapted for Indian medical practice and tropical districts.

208, Blackfriar's-road, London, S.E.
May 15th, 1879.

DEAR SIR,—I have used your Mistura Bismuthi Comp. for the last ten years, and have always found it a most reliable and useful mixture—pleasant to take, uniform in strength, and keeps for any length of time without change. I can with much confidence recommend it to my brother practitioners, for in the *many thousands* of cases in which I have prescribed it, I can safely say that I have never met with one failure. I am sure the sale would be much greater if more generally known.

Yours very truly,
T. SANDERS WORBOYS, M. R. C. S., L. S. A.

To Mr. Sellers,

It is necessary to caution the profession against spurious imitations, which do not in the smallest degree represent this preparation. All orders should specify "Sellers' Mistura Bismuthi Comp.," which is protected under the Trade Marks Act.

Each Bottle contains the exact Formula on the Label, which is Copyright.

Sold in ½lb., 1lb., 2lbs., and 5lbs. bottles at 10s. per lb., by the Sole Maker and Originator.

JOHN SELLERS, Manufacturing Chemist, 17, FARRINGDON-ROAD, LONDON, E.C.

May be obtained through any Wholesale Druggist in the United Kingdom, India, and the Colonies.

Agents:—BOMBAY, CALCUTTA, MADRAS.

STEEL STEAM CANOES, STEAM GIGS, STEAM LAUNCHES, all of Steel throughout with patent 3 cylinder "Compound and High Pressure (combined) Expansive Engine," convertible from the latter into the former by the one Lever that solely controls its motion, having no dead-centre and *capable of instantaneous reversal* while running at the highest speed. Portable Folding Boats, Corrugated Iron Sheds with patent Pillars, Portable and Stationery 2 and 3 Cylinder Engine, and Road Locomotives. For full page illustrated advertisement, see February, March, and April numbers.

Light draught Steel Barges or Flats adapted for the carriage of Produce in Inland Waters, Creeks, Shallow Rivers and Canals with very powerful little "Tug Steamers" of light draught, and having four Propellers or Paddles and twin Propellers. Seaworthy Launches, &c., &c.

FIRE BRICKS.

RANEEGUNGE FIRE BRICKS as supplied to Government and the various Railways, Iron Works, Coal, Gas, and Steam Navigation Companies. Price,—Rs. 9 per 100.

Extract from Official Report of tests made at H. M. Calcutta, by THEODORE W. H. HUGHES, ESQ., F.G.S., A.R.S.M., Officiating Deputy Superintendent, Geological Survey, India.

"*The Fire Bricks tested by me were furnished by the Firm of Messrs. BURN & Co.* * * * *The materials from which they are made are very refractory and capable of resisting high temperature without sensibly fusing.* * * * *That compared with Stourbridge Fire Bricks are somewhat superior.*"

The specimens were subjected to a temperature of over 3,000 degs. Fahr., the smelting point of Cast-iron being 2,786 degs. Fahr.

Apply for the above and for Raneegunge Salt Glazed Stoneware and imperishable Drainage Pipes to

BURN & CO.,
7, Hastings-street, Calcutta, or Raneegunge Pottery Works, Raneegunge,
E. I. R., Bengal.

SWINBORNE'S CALVES FEET GELATINE
IS MOST NUTRITIOUS.
Invalids and Infants should take Swinborne's Isinglass in Milk, Wine, or Broth.

ABYSSINIAN TUBE WELLS.

MR. GEORGE HAWKESLEY, 420, Caledonian-road, London, N., is the sole Licensee for these Wells in India. All applications should be made to him, or to

C. J. BARTER,
Tuticorin.

but state what I know from personal experience and information. We had better call on the children of the soil, they ought to be able to set us right on such subjects. We are here as strangers, simply concerning ourselves with such things as we can turn to account, and then leave all behind us when we retire to rest. The fruit on which the prickles are large and somewhat widely separated, gives the most pulp or edible substance on the seed, while that on which the prickles are close, has only a meagre quantity of pulp on the seed—just as with the custard-apple. The greater the division of the squares on the surfaces, the better the fruit, while that which is close marked on the surface is but very indifferent.

OBSERVER.

CINCHONA NURSERIES.

(To the Editor of the Ceylon Observer.)

SIR,—Your correspondent "Verbum Sap," in recommending seedlings to be picked out 6in. by 6in., seems to overlook that (allowing for stumps, paths between beds, &c.) only 100,000 plants per acre could be planted. How would many of us manage here, who have two and three millions of seedlings to put out, for acreage?

I have tried corrosive sublimate: it is very useful, applied to beds *before putting in the seed*, to kill grub, but dangerous to apply after the seedlings are up (as Mr. Wilton at Kew will, I believe, agree).

As to planting, my greatest success has been with plants 1½ to 2 inches high. I find they suffer less both from wind and sun, and have now far surpassed plants 8 inches to 15 inches planted at the same time.—Yours truly,

Agra Patana. R. W. N.

BLACK ACACIA.

(To the Editor of the Ceylon Observer.)

SIR,—Your correspondent "Terræ Filius" is mistaken in supposing that this tree seeds in Nuwara Eliya. It buds yearly, but the blossom very seldom opens, and I don't think it has ever been known to bear a single pod of seed. Propagation from the root is very well if a few plants only are required, and the earth must be dug, or the root in some way brought to the surface before plants can be obtained. It is not like the common wattle in this respect.

As to its "voracious habit," I know an instance in which trees eight years of age have penetrated the soil to a depth of 20 feet, and that in patana land where the subsoil had never before been opened by any root. If it is desired to plant very close to the black wattle, it is only necessary to cut a drain or trench by the side of them, when the roots not being able to spread laterally will penetrate the subsoil.

Your correspondent refers to the parasite with which this tree is often infested, but should remember that it is only from years of neglect that this occurs. The wood is tough and stringy, and suitable even for shafts and wheels, and is very ornamental in furniture and cabinet work. The bark of the tree is used for tanning, and quantities of it are, I believe, shipped from Australia for that purpose.—Yours truly,

EXPOSED LAND.

BOILED HORSE GRAM.

(To the Editor of the Madras Mail.)

SIR,—I heard from a friend of mine, regarding the authenticity of whose information I have no reason to doubt, that in one of the annual reports of the Sydapet Farm it is stated that boiled horse gram, though in other respects excellent and beneficial to horses, is open to objection on two grounds:—

1st.—In boiling, a good portion of the substance of gram passes off with water strained away from gram before it is given to the horse.

2nd.—It is heating and productive of many diseases.

The soundness of the first objection must be patent to all, but, perhaps, it is not a very weighty one, as it only concerns the question of economy, and as, with a little care, it is possible to reduce the wastage to a minimum. As regards the second objection, it is not uncommon that, especially in hot weather, horses from excess of heat, caused by boiled gram, get what are technically known as purigo, ring worm, mange and lice, ulcers, &c. To avoid this it has been suggested that gram soaked in water should be substituted, particularly in hot weather. But it is the belief among the natives that this would produce colic, inflammation of bowels, &c.

I therefore request that you or any of your numerous readers will be so good as to state whether raw gram soaked in water is a good substitute for boiled gram, particularly in hot weather, and if it is not, whether there are any means of mitigating the heating quality of boiled gram.—Yours, &c.,

Seringapatam. S. R. S.

GUTTA PERCHA.

(To the Editor of the Ceylon Times.)

SIR,—In answer to your correspondent, and because I consider the product likely to be a valuable one in Ceylon, I will endeavour to answer his queries.

The gutta percha of commerce is known as the *gutta taban*, and, to botanists, as *Dichopsis gutta*. Mr. Munton, the Superintendent of the Singapore Botanical Garden, who has written some notes on this product, will probably supply seed to those requiring it, its habitat is Perak and Malacca, and it will grow from the plains to an elevation of 3,500 feet; each tree will yield about 16 lb., the gutta is worth about 70 cents. a lb.; as it has a very long tap root, it must be transplanted when the plants are very small, or, better still, planted at stake; in obtaining seed, care must be taken to get the gutta taban as there is another variety closely resembling it, exuding a very watery milk and worth only a quarter of the other; the leaves of this spurious kind are shorter and broader and more ovate in outline, and the wood is much whiter and softer.

Another gutta, closely allied to caoutchouc or India-rubber, is a large woody climber, indigenous to Perak. There are two kinds, one having a very dark, coloured, corky bark, and the other a smoother and lighter bark; the former is the more valuable. To obtain the milk the stem is ringed at intervals of 10 to 12 inches, and the milk is received in vessels placed to catch it as it flows, this (gutta senggarip) is not nearly so valuable as the gutta taban and the yield of milk is about half the quantity, but I believe is more easily grown than the tree. It is found in the Malayan peninsula. There are various kinds of gutta-yielding trees, but the two named are the ones most valuable to the grower. I hope these few remarks may induce others, better informed on the product than myself, to say what they know about it.

P. W.

The Indian Agriculturist.

CALCUTTA, AUGUST 2nd, 1880.

GOVERNMENT CINCHONA PLANTATIONS.

WE are not aware of any industry having assumed such vast proportions in such a short space of time, as has the cultivation of cinchona in India. The latest report of the Government plantations in British Sikhim, that for 1879-80, tells us that the extensions made during the year were 196 acres, and that the number of young trees so planted was about three-quarters of a million. This was at the rate of one plant to 11½ superficial feet. Besides these extensions, large numbers of plants were put out to replace those that had been uprooted for barking purposes. The above were principally *C. Succirubra.* At the same time it is satisfactory to observe that the extension of cultivation of the best class of plants, *C. Calisaya*, has not been overlooked. Of this valuable species and its hybrids no fewer than 88,862 plants were put out. At the same spacing these ought to have filled about 23 acres. The nursery stock, too, was attended to, there remaining at the close of the year 16,000 stock plants, and 403,000 young ones. Dr. King's recent trip to Java, at the instance of the Bengal Government, resulted, among other matters, in the discovery that the *C. Calisaya* yielded the richest and most valuable bark, and that too in larger quantity. In procuring bark from the "red bark" trees (*C. Succirubra*), considerable difference of opinion exists as to the best method, three plans being followed, *viz.*:—uprooting, coppicing, and thinning. The former of course necessitates the replanting of the land, the second makes it impossible to get a steady annual crop, as coppiced plants require time to recover themselves. The last mode is the best, as will be seen at a glance by any one acquainted with the habits of the plant; but whether it results in giving the best all-round yield over a series of years is a point not yet decided. It has, however, been satisfactorily shown, that in the case of the yellow bark (*C. Calisaya*), thinning is the best plan. This is another

point in its favour. We hope, therefore, to see this favorite *jât* more commonly planted. It requires no more attention than the others, and the chemical properties of the bark are very much superior to any other class of cinchona. The only extra cost is in the price of seed, but this is an infinitesimal item in the account current.

There seems to be a deal of ignorance flying about among planters as to the yield of bark per acre. In coffee we know exactly how many cwts. of berry may be looked for on an average, and we have a fair idea how many lbs. of tea an acre in full bearing and good "heart" will yield. But we seem to have no definite idea of the outturn of bark per acre per annum. In the reports we read that a certain plot produced at the rate of so many lbs. per acre, but we are not told how many years must elapse before the next crop is gathered. In the matter of new plants we must of course allow some time for the seedlings to assume the form of trees, and to be in fit condition for thinning, stripping, or coppicing. It would be an item of useful information, if the Superintendent of these gardens would tell planters how many years had elapsed since the preceding crop was gathered from mature plants. In this report we are told that from a plot of "100 acres of 11-year old trees uprooted, the average yield of bark of all kinds was 1,680lbs. per acre." If another period of eleven years must elapse ere a fresh crop can be collected, we arrive at the conclusion that the average annual outturn of that plot is 153lbs. per acre. Another plot of 26 acres of 10-year old plants yielded 1,482lbs. per acre, and a third, also of 10-year old, gave 1,560lbs. so that we may say the annual outturn of these was about 152lbs. per acre. At the prices obtained in London for this article, such an outturn ought to pay well. Hitherto the manufacturing department has been confined to the production of a cheap substitute for quinine, and which has become known under the name of the Government febrifuge. This consisted of several ingredients, the best mixture having latterly been found to consist of "four parts sulphate of quinine, eight of sulphate of cinchonidine, and nine of sulphate of cinchonine." Previous compounds resulted in a febrifuge which, while of great value as a substitute for quinine, in fevers frequently produced a feeling of nausea in the patient which was found to operate materially against its use. The above mixture was, after several trials, found to be a vast improvement on all others. The nauseating quality being almost entirely eliminated without impairing the value of the compound as a curative agent for fevers.

In noticing the corresponding report of these plantations last year, we pointed out the fallacy of the bark being, for purposes of manufacture, valued at its net cost price, instead of at the price it would have realized in open market, and we would again draw the attention of the authorities to this point, as we observe it is repeated in this report. A small quantity of sulphate of quinine has already been made by Mr. Gammie, the intelligent Superintendent of the factory, and this, we are told, has been pronounced on analysis "to be equal to that of the best European makes." With such a future before this industry, we are not surprised to observe that it is being freely taken up in various parts of India and Ceylon.

THE OPIUM REVENUE.

THE opponents of the opium traffic had their innings in the House of Commons on the 4th of June, and a long and warm debate took place, with the usual lack of result. Both its length and its heat were chiefly due to the Secretary of State for India, who, after confessing that he knew little or nothing about the subject, having only had three weeks of office and no time to take up the opium question, managed nevertheless to say a good deal about it and very effectually to ruffle the equanimity of the opponents of the traffic on moral grounds. If he had, after confessing his ignorance, promised to give the subject his attention when he had time to do so, there would have been an end of the discussion. But it is hardly to be regretted that he allowed himself to talk, and talk freely, and that "with that ingenuous courage which," said the Prime Minister, "is characteristic of him almost beyond any other man in this House," he expressed some candid contempt for the "cheap morality" which would abolish an evil (admitting the evil of it) which the English have introduced into India, but would abolish it at the expense of the Indians. It should not be forgotten by the reformers, that we have established in India a very costly machinery of government, far too costly for the country; that we have been able to carry on this government by means, in a great measure, of the large contribution to our revenue which our power on the ocean enables us to draw from China; that it is not the people of India, but their present rulers and the people of England who supported Lord Palmerston in his China war, who are responsible for the opium traffic; that it is not the people of India who want the opium money, but England that wants it to enable her to maintain her Indian Empire without paying for it; that if we give up our opium revenue, the people of India cannot by any endurable fiscal means be made to contribute a substitute; and that therefore, if the opium reformers insist on our giving up the opium traffic, they must do one of two things—either get England to make up the deficiency in the Indian revenue, or show us how to govern India for several millions a year less than our present system of Government requires. Now every one admits that the connection of the Indian Government with the opium traffic is open to serious objections, and if, as Mr. Gladstone put it, the people of England will submit to an addition of 3*d*. or 4*d*. to the income-tax and send us the proceeds—that is to say, if England will cut seven millions away from our home charges, then the Indian Government will gladly give up its opium revenue. What earnest reformers may say, however, is that they are bound to denounce what they regard as an evil, even though they may not be able to show us the practical way to get rid of it. Enough that it is an evil; get that acknowledged, and then let Government, as best it may, find *some* way of abolishing the evil. This is an intelligible enough position for mere moralists and preachers. It is the preacher's business to denounce evil and warn the sinner to put the evil away from him under unspeakable penalties, and it is the sinner's business to get over the difficulty of dispensing with it. But though vague denunciations of the opium traffic may be proper enough in the pulpit, something more than vague denunciation is expected from a legislator speaking from his place in the House of Commons. What we want from a Member of Parliament is, that he will show us the way to get a less objectionable source of revenue than our present opium traffic is. But any one who attempts to show us that, very soon gets to see the enormous difficulties that surround the whole question, and learns, as a general rule, to hold his tongue about it.

While it is readily admitted that there are objections to the manner in which the Government of India is connected with the opium traffic, and while there is no doubt that there are evils produced by it, we are not prepared to admit that the Government of India is so peculiarly guilty as Mr. Pease would have us believe. We do not see that this trade is so much worse than the spirit licensing trade at home, about which much less is said. At home we license shop-keepers to enable them to retail wines and spirits to the masses, and we have little hesitation in affirming that the spirit trade at home does more harm to, and entails more misery upon, the people of Great Britain, than can be affirmed of the opium trade as regards the Chinese. But this is ever the case; we fail to see the beam that is in our own eye, while we have a keen appreciation of the mote in our neighbour's. We do not think that these would-be philanthropists will succeed in putting a stop to the traffic. But there are other two considerations which should not be lost sight of in looking at the revenue obtained from this source; and these are—the growth of the poppy in China, and its extending cultivation in Persia. With regard to the quantity of land under the poppy in China, it is of course impossible

to speak with any reasonable approach to certainty, but there can be no doubt that large and increasing areas of land are year by year put under cultivation, and this in spite of the half-hearted orders from Pekin regarding the growth and consumption of the drug. These orders, we know, are to a large extent issued to blind the foreigners to the real intention of the Mandarins, for while we find, on the one hand, these strict commands totally inoperative, on the other we find the cultivation of the plant winked at by the officials, and our merchants are finding the China made drug opposing them in the market. True it is inferior and does not realise so high a price as the Indian article, but this is only a matter of detail. The quality will improve, as we know the quantity is increasing, and some day—not very far off—we may find our revenue seriously interfered with. With regard to Persian opium, we are in less doubt, as we know exactly how much goes round in the mail steamers from the Gulf. Last year 7,000 chests were forwarded to China, and the estimate for the current year amounts to 10,000 chests, which quantity is equal to about 18 per cent. of our supply. We know how the percentage of Indian tea is gradually gaining on the China supply, and we may reasonably expect the same result from this drug, which the Persians are cultivating and making with great care. At first the price obtained for the Persian drug was low, but it has increased in value with marvellous rapidity, and we may expect to find it rivalling the Indian article in value, in a very short time. Where then are we to look for a fresh source of revenue in the event of this source drying up? We look hopefully to salt. A great cry has been made over this tax too, but only by those who are ignorant of the lightness of its incidence. Sir John Strachey's one beneficial act to India has been his salt scheme. The abolition of the salt patrol line has been practically effected, and it now only remains to complete the equalisation of the tax throughout the land, in which consummation we anticipate the commencement of a steadily increasing consumption of this necessary of life. At the present moment the consumption per head in India is not more than 40 per cent. of the corresponding consumption in the United Kingdom, and if the generally reduced rate of tax, coupled with a cheaply manufactured article, leads to an extended use of the commodity, we may look forward with confidence to the future, even if it embraces the total abolition of the China opium trade.

This opium question may be profitably examined from the point of view of the Indian cultivator. A cry is frequently raised that he is ruined by the growing of the plant, inasmuch as the whole business being a Government monopoly, a certain amount of *zoolum* attaches to everything connected with it. There is possibly just as much truth in this idea as to keep it afloat; but, that the cultivator grows the poppy under compulsion of any sort, we most emphatically deny. The only time when the ryot may possibly be subjected to a little pressure is when the plant arrives at that stage when the crude juice is in a fit state for extraction. At this time it may sometimes be necessary to exert a little pressure to overcome the ryot's laziness and indifference, and his apparently natural habit of doing everything in as slovenly a manner as possible, for all who know his character well, will bear us out in the remark that if there be nine right ways of doing a thing and one wrong way, he will somehow contrive to find out this latter and pursue it with a zeal worthy of a better cause. At this stage of the process the utmost care is necessary, in order that the result may be a good and carefully prepared article. As to compulsion being exercised in inducing him to grow the poppy at all, there is not an atom of truth in the statement. The cultivator makes a large profit out of it, and he is not so blind to his own interests as to refuse to take advantage of such an opportunity. He pays a very materially enhanced rent for land for the cultivation of the poppy, and he would not do this if he did not see his way to reimburse himself from the crop. It is also affirmed that the cultivation of the poppy is one cause of famines, as much land is taken up with it which would be much more usefully employed were it under food grains. This is likewise a fallacy, as the amount of land under poppy is only *one-quarter per cent.* of the cultivated land of India; so *that* argument falls to the ground. In fact all the arguments now against the trade are futile, with the exception perhaps of the ethical one with which we have dealt already.

BAMIEH COTTON.

An exceedingly small measure of success seems to have followed the recent attempt to introduce the Bamieh cotton from Egypt into India. In a very large number of instances, the attempt turned out a complete failure, the plant giving evidence that the climate was not adapted to its habits. A goodly number of experiments were made in Upper India, and these on the whole seemed the most promising; that at Saharunpore, conducted under the careful management of the late Mr. Duthie, is particularly to be commended. Notwithstanding the comparative failure of these trials, we think the attempt to introduce this valuable cotton ought not to be given up, and for the following reasons. The greatest failures took place either under the management of gentlemen comparatively unacquainted with agricultural pursuits, or, where failure occurred, under the hands of more intelligent experimenters, under climatic influences of a deleterious nature. For instance, we find a splendid crop in one locality perfectly ruined as soon as the pod commenced to form, by heavy and persistent rain, clearly showing that the experiment had been tried at a wrong season. Had the crop been planted, say, a month earlier, the result might have been vastly different. Again, the value of the fibre makes it a matter of moment that we should not thus lightly throw up the scheme. The produce was valued by eminent merchants in Bombay as worth 9½*d.* per lb. in London. Now, ordinary Indian cotton is not usually worth more than 5*d.* in London, and besides, this new variety yields more freely than Indian cotton.

The manager of one of the cotton mills of Cawnpore stated that the staple was so long and good that there was no machinery in India adapted to spinning it, and he added "such cotton is used in England for counts ranging between 100*s.* and 200*s.*, and requires particularly delicate machinery;" whereupon Mr. F. N. Wright, Officiating Director, Department of Agriculture and Commerce of the N.-W. P. and Oudh, says—"This report is not encouraging as to the advisability of extending the cultivation of this breed of cotton," and receives a well-merited rebuke from Mr. A. O. Hume, for a remark so wanting in commercial insight. The cotton is so very good that it is not advisable to cultivate it! It is so very much superior to anything we have ever known in India, that we had better have nothing more to do with it! During the American war, when the vast crops of the United States were denied to Lancashire, and when almost the only cotton reaching England was the exceedingly short-stapled variety of India, the spinning machinery was speedily adjusted and adapted to suit the inferior article; and surely if an article markedly superior were offered, the spinners would scarcely grudge the trouble and expense entailed in adapting their machinery to suit its manipulation. It may be true that a considerable time might elapse ere India could produce counts up to 200*s.*, but there would be no difficulty in finding a market for this cotton in Lancashire and Glasgow.

An interesting memoir, translated from the French, is included in the Government Report, whence we glean these particulars, and in this is discussed the genesis of the new species, the generally received opinion being that it is the result of a hybridisation between the common Egyptian cotton (*Hibiscus barbadense*) and a plant known in Egypt as Bamieh (*Hibiscus esculentus*). This latter is well known in India as the *bhindi*, or lady's fingers, which is seen so frequently as a cooling vegetable on our dinner-tables, and this is considered an exceedingly interesting instance of hybridisation, the two plants being dissimilar in habits. Most of us have seen both growing. The cotton plant, although a bush, has all the characteristics of a tree, as to its modes of throwing out its lateral branches; the *bhindi*, while throwing out many laterals, does not do so at right angles to the parent stem, the laterals all inclining to grow upwards and parallel with the main stem. If we compare the cotton plant to a miniature sycamore or plane tree, the *bhindi* might be called a miniature poplar as to habits and style of

growth. Another marked dissimilarity is in the shape of the relative seed-pods, the cotton seed pod or ball having not the slighest resemblance to the *bhindi*, which is the seed-pod of the *Hibiscus esculentus*. The result, however, is a cotton pod, without any trace of the *bhindi* in its structure. A little surprise is expressed at such an instance of hybridisation between two plants so unlike in habits of growth; but there is another illustration of a similar kind in the hybrid tea-plant. The two plants from which the hybrid is formed are *Thea Sinensis*, the common China variety, and *Thea Assamica*, the Indian indigenous variety. The former is to all intents and purposes a bush or shrub, about six feet in height, commencing to throw out laterals the moment the shoot shows above ground; on the other hand the latter is a tree, growing thirty feet high and growing with a clean trunk. The hybrid plant partakes of the characteristics of both, and is, like most hybrids, not so fruitful in the matter of seed as is the common variety. On this point the Bamich hybrid is anomalous, as it seeds more freely than either of its parents, although from those Indian experiments it seems to develop a tendency to allow the seed pods to rot before they arrive at perfection, at the slightest appearance of untimely weather. Notwithstanding all these drawbacks, we trust we have not seem the last of the experiments with this useful plant, as we are convinced that most of the so-called drawbacks would disappear if a little more care and intelligence were displayed in conducting the experiments, and if they were placed in the hands of men not already overburdened with official work.

IRRIGATION IN BENGAL.

IN his article on Indian Finance in the *Nineteenth Century*, Mr. Laing lays special stress upon the confusion introduced into the accounts by the intermingling of so-called productive public works with guaranteed railways, ordinary public works, local works, and so on, until even an expert is puzzled to discover the true result. Certain broad facts, however, are taken by him from the statistical abstract published annually by the Home Office, and these he makes the text of a disquisition on public works generally, according to his own views. The theory of productive public works which the *Statesman* has consistently advocated differs widely from Mr. Laing's simple principle of cutting down all public works to a minimum; but his figures are unimpeachable, and the immediate inference he draws from them cannot be gainsaid. It appears, for instance, that an expenditure of £9,650,000 on irrigation works during ten years up to 1878 produced no net return at all, but a dead loss of £67,000 a year, being the excess of working expenses and repairs over gross receipts. The papers more recently published by the Parliamentary Committee on Indian public works, while taking a wider range of years into account, showed much the same general results. Mr. Laing, therefore, infers that the Indian budget can never be really balanced while expenditure of this sort is classed as if it were no real burden upon the finances, as if, in short, it were reproductive in the financial sense of the word; for it is not denied that irrigation works, whatever their normal character, are reproductive in years of drought, though the saving due to them on such occasions cannot be brought to account, as a return on capital invested. Indeed, if the gains and losses of all kinds, due to canals, could be reckoned up, it is by no means certain that the balance would not be still more unfavourable than the mere comparison between direct expenditure and direct return. If the canals deserve to be credited with saving human life, and consequently obviating expenditure on relief works, in famine years, they also ought to be debited with the destruction of human life by fever, and the diminution of the cultivated area by the spread of *reh*. Dismissing, however, these more general considerations, let us examine the financial results of canal irrigation in Bengal during the year 1878-79, as recently given to the world in the *Gazette of India*.

The general results may be very succinctly stated. The capital sunk in Bengal canals stood at £4,937,319 in the year under review, but part of this was classed as belonging to 'ordinary' works, and the capital invested in productive works amounted only to £4,824,793. The net return upon this capital, *i.e.*, the surplus of income over working expenses, was £4,552 in 1878-79. In all previous years there had been no surplus, but an annual deficit. This return is less than one-tenth per cent. on the capital expended. But as this capital has all been borrowed and as interest at the rate of 4½ per cent. has to be paid on it by the Bengal Government, this income of £4,552 is a poor consolation to the provincial finances for the annual drain of £216,474 on account of interest. It may be worth while to turn aside here for a moment to admire the astuteness of the Imperial Government in dealing with canals under the last decentralisation scheme. All decentralisation schemes have for their object the conversion of local and provincial funds to imperial uses. The last and most notable scheme—that of 1876—swept some £400,000 a year into the imperial exchequer in this manner; but the gain becomes much greater if we count the saving effected for imperial purposes by the provincialisation of canals. The Government of India got rid of its bad bargain by the simple plan of attributing to canals a fictitious productiveness, and making provincial Governments responsible for the interest due on canal capital, with the minimum of help in the shape of an imperial subsidy. The interest being x, and the net return being xy, the amount of the imperial subsidy was fixed at something less than $x-y$; and obviously the value of this quantity decreases, as y increases, 1 remaining constant. The policy of canal decentralisation was to over-estimate y freely, and hence to reduce the subsidy to the lowest figure compatible with provincial solvency. Provincial Governments of course protested, and no attention was paid to them; but provincial irrigation reports are still found to contain reproachful allusions to the burden thus thrown on provincial finances. The Government of Bengal, in the present report, sadly reminds its officers that they must do their best to make canals more promising, for the local Government "is responsible for the payment of the interest on the large sums which have been expended on the irrigation works in the province." It is quite evident, however, from the tenor of the report, that no substantial improvement in the prospects of Bengal irrigation is expected. Were the net returns even quadrupled, they would still be the merest drop in the bucket, as compared with the huge interest charges. The loss which the province has already sustained on account of interest and unpaid working expenses, amounts to no less than £1,386,139; and it is plainly hopeless that any good management should ever reimburse the Bengal treasury for this money sunk in canals. For all *financial* purposes, it might as well have been sunk in the sea.

Bengal canals are divided into three classes, but one of these, the Hidgellee Tidal canal, is so small that it may be left out of consideration; and the Orissa, Midnapore, and Sone canals practically make up the whole area of irrigation. It might, indeed, be questioned whether the Orissa canals should be counted as primarily irrigation works, for some of them are brackish, and fit for nothing but navigation. Irrigation, however, was their original intention, and about two-thirds of the Orissa canal revenue is derived from irrigation fees. It is perhaps unnecessary to remark that these canals do not pay their working expenses. The latter amount to about £24,000 a year, and, by one method of calculation, the income from all sources appears to exceed this by £480, but if the calculation be made on the year's income as actually realised, the result is a deficit of £5,708 on the year's operations. This is irrespective of the charge for interest, amounting to £81,252 annually. The Midnapore canal is still more extensively used for navigation, and owes nearly half its income to this source. Income and expenditure here are more nearly balanced, both being about £17,000; but there was a deficit of £212 on making up the accounts of the year. This is in spite of the fact that the area irrigated was the largest hitherto recorded. The Sone canals alone shew a surplus; it amounts to £6,712 on a working expenditure of £37,050; but of course the fact is quite exceptional that there should be any surplus at all. During the brief existence of the Sone canal system, a capital expenditure exceeding two millions sterling has entailed a dead loss of more than £27,000. Navigation plays a comparatively small part in these canals; nearly all their earnings are due to irrigation; and it is noticeable that the area under

sugarcane in the Patna, Gya, Buxar and Shahabad districts, largely increased since the canals came into full working order. The number of maunds of coarse sugar exported from Shahabad by the East Indian Railway has been multiplied more than tenfold since 1873;—a result which ought to be remembered in estimating the profitableness of the canal, impossible though it may be to estimate such a result correctly. There can be no question that the value of the produce of the land has been greatly increased by the canals. A rough calculation, by way of example, might be made in the following manner.—The increase in the export of coarse sugar from Shahabad alone amounts to about 400,000 maunds, and coarse sugar may be assumed to be about four times as valuable as grain; thus the land which produced the cane yielding this sugar, was put to four times as valuable a use as if it had not been irrigated; and the gain in value of out-turn would be about 18 lakhs, or £180,000; and this, of course, from a single district. Without laying any undue stress upon a calculation couched in such extremely general terms, we may safely infer that the advantages of canal irrigation are much more extensive than the few heads of income which figure in annual reports. But it is with the latter only that the financier has to deal, and as a Government speculation, apart from all considerations of popular benefit not reducible to the formulæ of the ledger and balance-sheet, canal investments in Bengal are decidedly bad. We do not wish at present to enter upon the wider question of the advisability of canals for administrative reasons, but simply to regard them from the point of view of the holder of canal debentures (supposing such things to exist). So regarded, Bengal canals cannot appear anything but the most signal failure. Zealous canal officers, we are well aware, look upon any such avowal as rank heresy, in fact as an insult to the department; they are prepared to make a canal pay anywhere, even in Eastern Bengal, or in the rainiest districts of Assam. But if one questions these ardent partisans, it always comes out that they reckon upon a certain wholesome exercise of authority to persuade the people to take water. Left to themselves, the attitude of the people in this matter may be judged from what is written of the zemindars of Arrah, who, when a new distributary is to be made across their lands, "invariably offer the most obstinate resistance to the alignment originally selected, and to any modification of it that is proposed." This unwillingness of the people seems the more repulsive when one remembers the ingenuity, trouble and expense with which the water has been brought, not from the traditional sources of Indian irrigation, the perennial snows or the vast uplands of Central India, but from a stream fed in the low hills of Bundelkund, nourished by no great affluents, and patched so by the summer droughts that the water has to be sparingly distributed in May and June. Sentimental considerations, however, have little weight with the Indian cultivator; and we may boldly pronounce Bengal canals, as a financial speculation, to be a mistake. On their other aspects we may have something to say hereafter.

EDITORIAL NOTES.

It is said that Mr. Buck, Director of Agriculture, who is now on furlough, will accompany Mr. W. S. Halsey to Java, whither the latter is going on three months' leave. Thence Mr. Buck will proceed to Melbourne, where he is to represent India at the exhibition.

We have much pleasure in acknowledging receipt with thanks of the annual volume of the "Proceedings of the Royal Colonial Institute for 1878-79." It contains a large amount of interesting matter, and besides lists of members and other memoranda relating to the working of the Institute, there are nine valuable papers as subjects of interest to all colonists. Nor is India forgotten, as one of the papers read at the ordinary meetings is on "Life in India," by an old Bombay Civilian, and contains much matter for reflection.

There has just come into flower at the Edinburgh Botanic Garden, a plant of great interest to botanists. It is the *Rheum nobile*, or Sikhim rhubarb, and is believed by Mr. Sadler to be the first specimen of the plant that has flowered in Europe. It was grown in the open border, without any protection, from seeds received from Dr. King, of Calcutta, about seven years ago. It is about two feet high, and it is covered with beautiful straw-coloured tracts. A drawing is being made of this curious specimen, with the object of having it figured in the Edinburgh Botanical Society's Transactions.

The Report on the Revenue Administration of the Punjab and its Dependencies for 1878-79 is to hand, and is more than ordinarily interesting, so many details are given, and given in a succinct form that does not tire the reader, nor lead him to search for a grain of information among a bushel of verbiage. We have only to find fault with the lateness of the publication of this information. This was evidently brought about by a variety of causes. For instance, the first district report was received on June 7, 1879, but the last settlement report was not to hand till 22nd September 1879. The finished report reached the Lieutenant Governor on 3rd January 1880, and the usual orders were passed thereon on 17th March 1880. Surely it is not too much to expect a little more expedition in connection with such important matters which frequently lose their interest with their freshness. The land revenue collection amounted to Rs. 1,89,69,173, being Rs. 94,001 over that of 1877-78; while what is known as fluctuating and miscellaneous land revenue was Rs. 1,79,954 in excess of 1877-78. This latter consists of grazing dues, sales of wood, saltpetre, fees on licenses, fisheries, and sundry collections from various miscellaneous sources. The total excess over 1877-78 was, therefore, Rs. 2,73,958. Advances continue to be freely made for the purpose of helping cultivators to purchase bullocks and seed-grain. In the year under notice the amount so advanced was Rs. 1,62,467. The land under *rabi* cultivation was much less than in 1877-78, the crop having been 8,48,401 acres deficient; on the other hand, the land under *khurreef* crop was 22,74,701 acres over that of the preceding year. During the year the cultivators had two calamities,—the floods of August 1879, and a visitation of rinderpest and foot and mouth disease which destroyed about 30,000 cattle. Of the whole area of the Punjab, amounting to 1,07,010 square miles, only 36,656 or 34¼ per cent. were under cultivation. The experiments in improving the breed of cattle seem to be working well, the value of stock generally having materially improved, the only failure being with sheep, but renewed efforts are being made with a view to improve the breed of these useful animals.

Prices of food-grains were considerably higher, the demand for the war in Afghanistan doubtless having helped to bring this about. The efforts that were made to develop the iron industry of Kangra resulted in failure on account of the difficulty in procuring fuel. This is becoming a crying evil all over India, and the subject of *reboisement* is bound to become a prominent one ere long. Enterprise in silk seems to be on the increase, some home firms having established agencies for the collection of cocoons. Taken as a whole, the Report is encouraging, and it is satisfactory to note the impetus which has been given to agricultural improvements since the accession to office of the present Lieutenant-Governor, who deserves much of the Punjab for his enlightened efforts to improve agriculture generally.

Kurrachee seems determined to take advantage to the uttermost of the opportunities coming in its way through the completion of the Indus Valley State Railway, and is making great effort to improve its harbour. A contract to the extent of 4¾ lakhs has been entered into with a firm of contractors for the construction of a ship pier, and this is doubtless but a beginning. Kurrachee is favorably placed for intercepting the trade of the Punjab and of the Upper Provinces generally. The wheat trade of the Punjab is sure to assume large proportions shortly, and Kurrachee is likely to secure the bulk of the trade. The competition will in the meantime be between Kurrachee and Calcutta, Bombay being practically out of the running, for reasons which we will state further on. The distance from most of the Punjab stations by way of Kurrachee will save a railway journey of from 200 to 500 miles, an item that must tell in favor of Kurachee. Besides it appears that freights are

usually lower from Kurrachee than from Calcutta, the difference being frequently as much as two shillings per quarter, which, in most cases, would of itself make all the difference between profit and loss. The reason why Bombay is meantime out of the competition is that, by way of Allahabad and Jubbulpore, the distance is 281 miles longer than to Calcutta, and the double breaking of bulk, consequent on the Rajpootana narrow gauge section, makes cheap and expeditious traffic impossible. But for this break of gauge, a large amount of the grain traffic would clearly go that way. From, say, Umballa south to Cawnpore almost all trade would naturally find this the shortest and most economical route, and there can be no manner of doubt but that the entire narrow gauge section of Rajpootana will have to be replaced by a broad gauge line within a very few years, in order to meet the requirements of trade, the present system being utterly inadequate. To enable Kurrachee to meet this competition, she will have to improve her shipping facilities, and this she is evidently doing. In the hurry of all this wholesome competition, it behoves Calcutta to look to her railway and shipping facilities. These have been very materially improved of late by the erection of the jetties, but much yet remains to be done, as the jetties at present constructed are not by any means sufficient for the immense traffic of the port.

WHAT her coal-fields are to Great Britain, the superabundance of solar heat may some day become to India. It appears that, since May last year, a M. Mouchot has been carrying on experiments near Algiers with his solar receivers, and various important results have been obtained. But perhaps the most interesting results are those relating to the mechanical utilization of solar heat. Since March the receiver has been working a horizontal engine (without expansion or condensation) at the rate of 120 revolutions a minute, under a constant pressure of 3·5 atmospheres. The disposable work has been utilized in driving a pump which yields six litres a minute at 3·50m. or 1,200 litres an hour at 1m., and in throwing a water-jet 12m. This result, which M. Mouchot says could be easily improved, is obtained in a constant manner from 8 A.M to 4 P.M., neither strong winds nor passing clouds sensibly affecting it.

THE subject of the breeding of sheep, or rather of the improvement of the breed of our sheep, is at present under the consideration of the Government of the North-Western Provinces and Oudh, and, notwithstanding the attempt of Sir Ashley Eden to throw a wet blanket over the scheme, it is just one of those improvements which is not calculated to shock the prejudices of the ryots. If any glaring innovation be introduced to their notice, their prejudices are up in arms at once. Hence it is advisable in all proposed alterations and improvements affecting his very conservative individual—the ryot, that the thin end of the wedge should be very cautiously inserted. Now the great object in view is to improve his condition; and various plans are proposed with this object in view. These plans usually involve a demand for such improvements in the modes of cultivation as involve an expenditure of money quite beyond the power of the cultivator to furnish; hence they prove abortive. One demands that heavier ploughs be used in order to effect deeper cultivation. This means an expenditure out of all proportion to the ryot's ability; another wants heavy manuring, again seeking what the villager has not to give. For heavier manuring resolves itself into a question of his purchasing firewood, and putting his cow-dung to its legitimate use. But the proposal regarding the improvement in the breed of sheep is quite within his reach, at least with what help he will and must get from Government. Two things will be necessary;—the Government must provide a better class of rams, and, wherever these are introduced, all village rams must be castrated; and on the part of the villager, he must contrive somehow to feed them a little better. These two changes will effect a wonderful improvement in our sheep in a very short space of time. One object which ought to be kept in view is, the improvement of the fleece, and from experiments we have ourselves observed, we apprehend this to be as much a matter of feeding as breeding. The sheep are usually fed by being driven to the nearest forest land. There they are driven in the early morning by a very small boy, who brings them back at night. This boy usually passes the day sleeping, instead of driving his charge from place to place, and all that is required of the cultivator is that he should have his sheep driven by some one who will move them from place to place that they may enjoy fresh pastures, of which there is usually enough in these forests. Besides improving the value of his sheep in weight, the village farmer will have the satisfaction of increasing both the quality and quantity of the wool. In England the average weight of a fleece is six pounds, and here it is not more than three and-a-half pounds, and East Indian wool realises about a shilling per pound at home. From the immense herds one sees up-country, one would expect to find a large export trade done in wool, but there is little, and the only outlets for this wool are in the making of coarse blankets, and in the manufacture of *bunnath* cloth; but neither of these industries is carried on so largely as it might be, and as it ought to be, considering the demand that must exist for these useful articles, especially during the winter months.

TOO much importance can hardly be attached, now-a-days, to the subject of adulteration, especially in respect of food and drink, matters which so largely affect the domestic interests of the people. In France the practice of adulterating articles of food and drink is said to have been common long before it spread to England. But the French Government took prompt measures for the repression of the evil, and the severity of the law has been instrumental in suppressing the practice to a very great extent. In England, too, of late years, the subject has happily received more attention. Ever since the labours of the famous *Lancet* Commission and the startling exposures which resulted therefrom, public opinion has declared itself upon the subject which was thus forced upon the attention of Government. Scientific means were employed for the detection of the fraud, and the skill of the analyst was rapidly followed by the hand of the law. Legislation was called for on the subject, and now, throughout the British dominions, the penalties for adulteration are sufficiently severe, and, as a rule, rigidly enforced. To-day no publican dare adulterate his beer without rendering himself liable to a fine of £50, which is, indeed, the lowest penalty inflicted; while a dairyman found adding water to the milk he sells is mulcted to the extent of £10. These fines have frequently been enforced in full; but, notwithstanding the severity of the punishment, we are afraid that adulteration is still practised to a very considerable extent and in various forms. The importance of the question of adulteration has, we see, lately been attracting much attention in the United States, where the Committee on Manufactures, appointed by Congress, lately furnished a report, upon which has been prepared a "Bill to regulate the Manufacture and Sale of Articles of Human Food and Drink." We have not seen a copy of this report ourselves, but the *Japan Mail* tells us it "is long and interesting, and is predicated upon analyses made of many articles of food by Professor Collier, the well-known chemist to the Department of Agriculture, and other eminent scientists,—men of world-wide fame in their respective specialities." The disclosures made by Professor Collier and his *confrères*, respecting the extent to which adulteration is carried on in America, are said to be positively alarming. Some experiments were conducted with so apparently simple an article as coffee. The report informs us that six packages, each containing two small boxes of coffee berries, were purchased. The berries were then weighed, washed, and the turbid washings evaporated to dryness. By this treatment, added substances were removed, and the following table indicates the percentage of the total weight of berries:—

	Colored berries.	Uncolored berries.	Per cent. of difference.
No. 1	147	79	68
" 2	72	53	19
" 3	90	82	8
" 4	128	64	64
" 5	114	51	63
" 6	91	33	58

The residues were then treated, and left, when burned, "a yellowish residuum which contained in every case chromate of ead, phosphate of calcium (indicating bone black), and insoluble sulphate of barium. Those salts were added to these berries for the purpose of 'facing' them, and, by improving their appearance, to enhance the market value of the berries. These salts were in no case found in the residues of the uncolored berries."

The outlook for the lovers of "pure mocha," is not, under the circumstances, an agreeable one; but, as the *Japan Mail* remarks, they have at any rate the negative consolation that tea-drinkers are in an equally bad, if not worse, condition. Regarding the adulteration of tea, the report affirms that, "our own citizens have far surpassed the Heathen Chinee in successfully adulterating this article. Samples of what seemed good gunpowder tea—found in Washington market, New-York,—under microscopic examination, seemed to be fully one-half Prussian blue. In analysis only enough tea dust was found to impart a smell."

The *Rangoon Gazette* acknowledges the receipt of some Karen Hill tea and coffee grown by Mr. Petley, an enterprising resident of Toungboo. There is no doubt an admirable field here for the growth of tea and coffee, if our land laws were made more liberal. But Government is so chary of giving away any waste land now, only leasing it in small quantities, and even then making it difficult to get, that capitalists naturally shun having anything to do with land in Burmah; and, except for paddy cultivation, hardly any land is taken up for tobacco, tea, and coffee, all of which, it has been proved over and over again, would thrive in many parts of this province. It is to be hoped that with a "Liberal" Viceroy, and with Mr. Aitcheson removed to the Council, we may shortly have a more enlightened system of legislation with regard to land in British Burmah, and have the line of railway to the Toungboo frontier commenced without further delay. Private capitalists offered to construct this line some eight years ago, but were snubbed for their offer and told that the Government of India would in future construct all railway lines for itself. The consequence is that we are without any railway to Toungboo, and that our means of communicating with this district are as backward as when we first annexed the place in 1853. It takes in the rains about a fortnight for a boat to get to Toungboo, whilst the distance by rail, 180 miles, could easily be got over in a few hours.

It must strike all that if the red abandoned hills of many of the low lying districts had only been planted with jacks (*artocarpus integrifolia*) some years ago, the properties would now have become very valuable indeed, instead of being, as so many are, worthless eyesores. We hope that the proverb, better late than never, will be acted upon, and that planters will, if only for the sake of posterity, plant jack seeds throughout their low lying estates. There is some doubt as to whether it is possible to transplant young jack trees. We have seen this successfully done near Panwila, but we should advise that the seeds be placed in bamboo pots (the earth being mixed with Hora saw-dust to keep white ants away) and removed to the field when the plants are about 6 inches high. The best variety of jack tree is said to be that which produces fruit at the roots, such fruit selling for three to four times the price of the ordinary jack tree.

The State Legislature of New Jersey has passed an Act designed to encourage the growth of fibrous plants, including jute, ramie, flax, hemp, and various other plants and grasses grown elsewhere in the United States, or imported. Its principal features are as follows:—

For every ton of 2,000 pounds of *Abutilon avicennæ*, stalks grown in New Jersey, not less than 3 feet long, 5 dols.; for every ton of 2,000 pounds of what is known as rose, or marsh-mallow, not less than 3 feet long, and not more than one inch in diameter at the butt, 5 dols.; for every ton of 2,000 pounds of ramie stalks not less than 2½ feet long, 10 dols.; for every ton of 2,000 pounds of flax stalks for fibre of the ordinary lengths, 7 dols.; for every pound of decorticated or cleaned flax of first American quality, 3½ c.; for every ton of hemp stalks of the ordinary lengths, 6 dols.; for every pound of decorticated or cleaned hemp, of best American quality, 3 c. In each case fractions less than a quarter of a ton are paid for at the same rate. The bounties will cease the 1st day of April, 1885, or in the event of the total amount paid reaching 15,000 dols.

The London papers call attention to a remarkable "rig" which is now proceeding in medicinal opium. Is it represented that an Anglo-American Syndicate, controlling very large funds, is buying up all the drug that can be procured. There are said to be about 4,000 cases in existence, and the coming crop in Turkey is a short one which will only yield about 3,000 more. The speculators say they hope to run the price up to 48s., and they have already succeeded in putting it up in New York from 18s. to 26s. The medicinal journals say that this manipulation of the opium market should stimulate scientific enterprise to utilise Indian opium for medical purposes. At present the Indian drug is too refined and weak in narcotic force to be used in medicines; but perhaps this may be overcome.

It is stated by the Chief Engineer that the results of the irrigation operations in Bengal for the year 1878-79 were on the whole satisfactory. The receipts exceeded the working expenses by Rs. 45,523; thus for the first time Bengal irrigation has shown a profit which would have been greater had the outstanding balances been collected. Calculated by earnings of the canals, the surplus on the year's operations would be Rs. 2,66,758 as follows:—Orissa canals, Rs. 4,783, Midnapore canals, Rs. 5,134, Hidgellee canals, Rs. 36,880, and Sone canals, Rs. 2,19,961, total Rs. 2,66,758. "For the spread of irrigation in Orissa we must look to the extension of the distributaries and the completion of the canal system. In Midnapore the limits to which irrigation can be expected to extend have been nearly reached; further development must depend on the construction of reservoirs in the hills to supplement the supply in the river Cossye. On the Sone canals the eventual increase of the irrigated area is certain; but the rapidity with which it is likely to be developed will be dependent, in a great degree on the seasons and the amount of the rainfall; much will also depend on the speedy construction of village channels, and it is expected that the introduction of a satisfactory system of leases for long periods will have a most beneficial effect."

A planting correspondent writes to the *Ceylon Observer*:—"I find that *Uritusinga* is the largest form of *officinalis*, and not *Condaminea*: the latter coming second only. This is what McIvor says in his book, and what is still true in India. Those who are now planting *Condaminea* under the idea that it is the largest variety, are mistaken. What do you say to this? There can be no question that the large-leafed variety is what we must cultivate, and it is very important to know what it is called in India." [Howard was the first to send out *Uritusinga* to India.]

The cultivation of the ground nut appears to have been extensively carried out this year in the Bangalore district, and it is not unlikely that the outturn will exceed that of the Kolar district, which has always gone in largely for the nut cultivation. Some time last year the Government of India sent a circular round to all local Governments, pointing out the value of the nut as an item of export, and asking what steps should be taken to induce ryots to cultivate it more extensively; this has borne some good results; for, as we stated, the area of cultivation this year has been much increased. The cultivation of the nut is very profitable, and, once sown, a crop for each year for three years will be yielded. The oil is used by natives as an edible, while the cake is a fattener for cattle or poultry.

Fair dhollerah having passed into the sere and yellow leaf no longer possesses the charms she once did, and "Prima in Indis" is anxious to get up a trade in some other staple. The *Bombay Gazette* points to wheat, and says that ought to be their largest item of export. But Bombay is heavily handicapped against Calcutta:—

"The G.I.P. Railway which runs through the heart of the wheat country from Sohagpore to Jubbulpore and Nagpore, is in direct through traffic with the East Indian Railway to Cawnpore; the distance is less from Jubbulpore to Bombay than to Calcutta, by

168 miles. Yet it is cheaper to send it to Calcutta. The charges are as follows :—

			as.	p.	
Nagpore to Bombay,	520	miles	11	9	per cental.
Jubbulpore to Bombay,	616	,, ...	12	8	,,
Jubbulpore to Calcutta,	784	,, ...	10	3	,,
Cawnpore to Calcutta,	684	,, ...	11	0	,,

"This shows clearly how excessive the G.I.P. Railway charges are. Although the old excuse will doubtless be urged, of the extra expense this railway incurs through having to traverse the Ghaut, yet add 40 miles more to the distances of Nagpore and Jubbulpore for the extra expense of the Ghaut traffic, and it will still be seen the G.I.P. Railway rates are far in excess of the East Indian. Wheat is an article which has to enter into keen competition with other countries, and the slightest addition to railway charges takes away the small margin of the trader's profit."

The *Gazette* urges the Bombay Chamber of Commerce to take up the subject.

OFFICIAL PAPERS.

THE OPIUM OF PERSIA.

THE following memorandum is taken from a lately published report on the Persian Gulf Political Agency :—

For the last two years the Persians have shown unprecedentedly great activity in extending and improving the cultivation and growth of opium in the country. The heavy losses which they suffered on more than one occasion from their badly-prepared and adulterated stuff, and the tempting profits which they found were obtainable from better produce, have apparently impelled them to the course now taken. While a few years ago a case of Persian opium weighing 18 Tabreez maun. or 140 lb., would not fetch in China more than 280 to 350 dollars, it has recently realized from 500 to 615 dollars. This change cannot, of course, be attributed altogether to the improvement in the quality of the Persian drug, as prices are regulated by the state of the Indian produce and by the demand in the China markets. The Bengal and Malwa crops failed in the last two years, owing to drought and other circumstances, and the limited outturn, coupled with heavy speculation, tended towards the increase of prices. The prospect of the crops of the current year is said to be favourable, but the trade in opium is not expected to be very remunerative.

To return to the Persian opium, from the time the attention of the native merchants was attracted to the trade in this article about 25 years ago there has been, with two or three exceptions, a gradual annual increase in the production of the drug. But this increase has never before been so very considerable as to become prominently noticeable.

It was reported in 1859 that about 3,000 Shah maun, or 300 cases of opium were produced in Persia, and in 1861 that about 10,000 Shah maun. or 1,000 cases were expected to yield from the crops of the year, a quantity which was then noticed to be double the outturn of the previous year.

In the trade report of this Residency for the year 1874-75, the fluctuations of the annual estimated produce of opium in Persia from the year 1868-69 to 1874-75 were shown in a tabular statement attached to a special report on the subject. The largest produce for any one year did not exceed 2,600 cases (a quantity inappreciably small in regard to the demands in China), and in 1874-75 it had fallen to some 2,000 cases. In the following year there was a further decline, the exports amounting to about 1,899 cases. Since 1876-77, however, a re-action appears to have taken place, as in that year 2,570 cases were exported from Bushire and Bunder Abbass alone

In the early part of 1877 78, the probable yield of the crops was estimated at 3,500 cases, but the actual number exported from Bushire and Bunder Abbass amounted to 4,730 cases.

Last year (1878-79) the outturn was stated to have been 6,700 cases, while 5,900 were exported from these ports.

The probable yield of the crops of the current year 1879-80 is at present estimated to be as follows :—

	Shah maun.		Cases.
In Khorasan, about	14,000	equal to	950
,, Kerman ,, ...	4,500	,,	300
,, Yezd ,, ...	15,000	,,	1,000
,, Ispahan ,, ...	37,000	,,	2,400
,, Neereez ,, ...	[illegible]	,,	400
,, Shiraz ,, ...	20,000	,,	1,300
,, Kazrun ,, ...	1,500	,,	100
,, Shushter ,, ...	1,500	,,	100
Total ,, ...	99,500	,,	6,550

In addition to the above 6,550 cases of opium, about 8,000 Shah maun. or say 550 cases are expected to come to Yezd from Herat, making the whole stock 7,100 cases. The Shushter opium is sent through Mohammerah direct, and sometimes *viâ* Bushire to Muscat for transmission to Zanzibar; but a part of it is supposed to be smuggled into the Indian frontier-provinces *viâ* Mekran Beluchistan. Thus 7,000 cases are expected to be available during the current year for export, through Bushire and Bunder Abbass, to China and England.

Small quantities of opium are said to be grown in Tehran, Tabreez, and Kermanshah, but these mostly find their way to Europe *viâ* Turkey, Smyrna being, it is alleged, the port where it is mainly taken to, and where it is mixed with the local drug and forwarded to the Continental markets.

Opium is made up into cakes varying in weight from ¾ to 1½lb., and in number from 96 to 102 or more; and these are packed in fig or vine leaves and sometimes in poppy seeds or stalks, into cases containing each from 10½ to 11 Shah mauns., a Shah maun. being equal to about 13¼lb. English.

The object in so packing in cases, as regards weight, is that the contents after the deficiency caused by the drying up in course of transit, which is calculated at from 5 to 10 per cent, may realize at destination, China, one "picul," which is about 135lb. Another reason is that the weight is arranged for convenience of carriage by pack animals,—generally mules employed in these regions.

About 5 6lb. of the produce of opium prepared in Persia are intended for China. The drug suitable for that market being required to be fine and prepared with oil, and not rich in morphia, permits its being swelled up with foreign substance, and thus being, as far as practicable adulterated to the extent to preclude discovery by the modes of testing or "touching" used in China.

It is said that pure and superior opium, though not so finely manipulated, has been rejected in China, while the fine opium containing admixtures has found favour and fair market.

The preparations made for the China mats, being, say, of a quality of 80 "touch" (containing 80 per cent. pure juice and 20 per cent. foreign substances) yield from 9 to 10 per cent. morphia.

The preparations for England which have recently been specially made pure, and which have come into favour in Europe and America, have, it is said, yielded morphia averaging about 12 per cent.

The average price for fair quality of opium suited for the China market has been for the last two years about Rs. 950 per chest; and for the special preparations for England, about one hundred rupees more.

To these are added the charges of transit and other contingent expenses from the place of product to the port of shipment, amounting to about Rs. 30, and further a custom and octroi or other duty of about twenty rupees payable by a Persian, or 5 per cent. *ad valorem* by a British or other foreign merchant.

G. LUCAS,
Uncov. Assist. to the Pol. Resident,
Persian Gulf, Bushire.

MEDICINAL PLANTS IN INDIA.

FROM A. JAMIESON, Esq., Superintendent, Government Botanical Gardens, to R. W. BARLOW, Esq., Commissioner of the Nilgiris, dated Ootacamund, 1st April 1880, No. 498.

With reference to paragraph 8 of G.O. No. 1992, dated 3rd October 1879, and G.O. No. 295, dated 8th ultimo, and your endorsement thereon, I have the honor to report that the utmost care and attention continues to be bestowed on the medicinal plants under cultivation in the Government gardens under my charge.

2. In addition to Jalap (which continues to thrive most satisfactorily), the plants noted in the margin are being propagated and planted out as rapidly as young plants can be produced. Of these the most important are Peppermint and Rhubarb.

Peppermint.	Lavender.
Rhubarb.	Digitalis.
Rosemary.	Taraxicum.

3. *Peppermint.*—After fully a year's trial, I have abandoned the cultivation of Peppermint at Ootacamund, the climate being too cold to produce a luxuriant growth. The plant grows rapidly during the autumn months, but becomes stunted and withered as soon as the dry frosty weather sets in. I am, therefore, having the entire stock transferred to the newly-formed nurseries in the Kalhatti Garden, where we have a more forcing climate and an abundant supply of water at command throughout the year. The present year's crop of Peppermint will, I believe, yield several pounds weight of oil when distilled.

4. *Rhubarb.*—The stock of Rhubarb plants have not, I regret to add, increased so rapidly as I anticipated. The original plant having not yet borne seed, the propagation has in consequence been confined exclusively to the division of the older plants. In June last year, I put out one plant in the Kalhatti Garden, which has grown very much stronger than the plants in the Ootacamund Gardens. The plants now in Ootacamund will be transferred to Kalhatti as soon as the weather is favorable for transplanting, and every means adopted to increase the stock as fast as practicable. At Banbury in England, where medicinal Rhubarb has been cultivated for many years, it is considered advantageous to allow the roots to remain in the ground until they are six or seven years old, but they are seldom allowed to attain more than four years' growth, at which age I have no doubt our plants will commence to yield a return.

5. *Rosemary and Lavender* grow freely in a friable loamy soil in Ootacamund, and are easily propagated by cuttings. When the plants already put out have made a sufficient growth, they will be cut over, and the produce dried and forwarded to the Medical Department for distillation.

6. *Taraxicum and Digitalis* grow so freely in Ootacamund as to require no special care. The demand for these drugs by the Medical Department is at present supplied from plants growing spontaneously in the gardens. Should the present demand be largely increased, it could easily be met with little expense in cultivation.

7. *Jalap.*—With a view to further extending the cultivation of the valuable drug, one-and-a-half acre of land immediately within the northern boundary of the gardens have been broken up, terraced, and manured. The land will be first cropped with potatoes, then planted up with Jalap. When it comes into bearing there will be a sufficient area under Jalap to meet the requirements of the Indian Medical Department

8. In August last year, I received from Surgeon Major Bidie a packet of seed called Barbung, believed to belong to a species of plantago, and which Dr. Bidie says is largely used in Persia and Central Asia as a cure for dysentery. The seed was sown immediately after receipt and germinated freely. As soon as the plants were large enough, they were transplanted in the Kalhatti nurseries, where they are making satisfactory progress. When the plants have flowered and seeded, specimens and a packet of seed will be forwarded to Dr. Bidie for identification and analysis.

9. During the present year I hope also to undertake the cultivation of the following drugs, all of which are in considerable demand by the Medical Departments, and I have no doubt will be found to thrive either at Ootacamund or Kalhatti:—

Aconitum Napellas.	Hyocyamus Niger.
Atropa Belladonna.	Convolvulus Teammonia.
Colchicum Autumnale.	Artimesia, sps.
Gentiana lutea.	Valerians officinalis.

THE GROWTH OF THE CORN TRADE OF ANTWERP.

SOME thirty years ago the production of breadstuffs in Belgium generally exceeded the demand for home consumption. We exported Belgian grain occasionally, and after the repeal of the corn laws in England pretty regularly. Imports of foreign grain took place only on a notable scale in case of a failure of crops, and on the whole our grain business was quite unimportant.

This could, however, hardly be otherwise.

The corn trade had until then been prevented from developing, by injudicious legislative interference. The measures which were decreed in turn for the protection of the producer and of the consumer proved fatal to both. The sliding scale, imported from England into France and Belgium, acted as a prohibition of imports and combined with prohibitions of exports which were always impending whenever there was a serious apprehension of scarcity, introduced an element of uncertainty into every transaction connected with the corn trade which produced a disinclination on the part of the merchant to import, and discouraged production beyond the wants for home consumption.

Railways and other artificial means of communication were still in a relatively rudimentary state, and the cost of transport of such a cumbrous article as grain, to any great distance, was enormous. The development of industrial life was stunted by the protective system flourishing everywhere, the working classes were mostly poor and indifferent consumers, the growth of population slow.

The economical reforms inaugurated in England and imitated on the continent rather timidly at first, but by-and-by at a more rapid pace, especially since the conclusion of the commercial treaty between France and England in 1860, wrought a complete change in this situation.

We witnessed then a marvellous increase of the industrial activity and of the international exchanges, railways were constructed, canals dug, rivers regulated, ships and steamers built and their machinery improved, capital was rapidly accumulating and credit expanding, wages were rising, and the population fast increasing. The home production of cereals grew more and more insufficient, first in the United Kingdom, afterwards elsewhere, and the corn trade acquired gradually that volume which is one of the greatest marvels of the age.

Belgium was one of the first countries on the continent that adopted the free trade policy of England, and although the reforms were not here so rapid, nor so sweeping, the effects were hardly less wonderful than in the United Kingdom. Among the many benefits we reaped from the reduction of tariffs, not the least important was the development of the corn trade which, promoted besides by the eminently favourable topographical position of Antwerp, made rapid progress.

As we stated above, we had as good as no regular corn trade some thirty years ago, and Antwerp has now already become one of the largest corn markets of Europe. This fact is of so recent a date that it may not be so generally known abroad as it would seem desirable for this market. Some statistics about the growth of this trade and a few remarks respecting its prospects of future progress may therefore be a welcome contribution To offer some is the object of this notice, and we should be happy if, by rousing or stimulating the attention of shippers, it could in any measure promote the direct intercourse, especially between distant corn-growing centres and our port.

What our trade was formerly, and what it has become in the relatively short space of time which has elapsed since the inauguration of the free trade era, will be best shown by the comparison of our imports in the ten years from 1845 to 1853, and in the last ten years which we give in the two following tables:—

Imports of Cereals into Antwerp from 1844 *to* 1853.

Year.	Wheat.	Rye.	Barley.	Oats.	Maize.	TOTAL.
	Hect.*	Hect.	Hect.	Hect.	Hect.	Hect.
1844 ...	101,090	67,230	3 1,230	19,500	...	519,050
1845 (1) ...	768,720	87,000	253,620	7,980	...	1,117,320
1846 (2) ...	1,741,440	811,920	185,100	32,490	...	2,773,950
1847 ...	1,453,500	1,037,670	104,120	17,370	...	2,612,660
1848 ...	151,920	64,860	72 150	2,010	...	290,940
1849 ...	127,521	22,388	28,541	400	...	178,853
1850 ...	42,553	43,477	60,602	......	...	146,632
1851 ...	197,113	53,190	64,368	5,977	...	320,648
1852 (3) ...	829,607	264,298	110,923	6,911	...	1,210,838
1853 (4) ...	820,095	322,714	178,041	......	...	1,320,850
	6,233,559	2,777,747	1,417,793	92,638	...	10,521,742
Averages	623,356	277,775	141,779	9,264	...	1,052,174

(1) First appearance of the potato disease.
(2) Failure of crops all over Europe which pushed up prices of wheat to Frs. 61·25, and of rye to Frs. 46·75 per 100 Kos.
(3 & 4) Failure of crops.

Imports of Cereals into Antwerp from 1870 *to* 1879.

Year.	Wheat.	Rye.	Barley.	Oats.	Maize.	TOTAL.
	Hect.	Hect.	Hect.	Hect.	Hect.	Hect.
1870 ...	2,020,179	411,112	853,675	1,321,297	...	4,639,263
1871 ...	5,547,477	1,591,887	1,315,672	2,374,162	...	10,832,198
1872 ...	2,128,275	362,503	210,377	2,000	...	2,703,155
1873 ...	3,868,221	860,183	1,480,618	526,544	...	6,735,586
1874 ...	4,329,380	1,069 972	1,478,277	1,187,621	...	8 065,250
1875 ...	2,387,012	736,149	1,281,198	733,419	...	5,138,078
1876 ...	5,452,183	1,016,169	1,499,312	1,556,675	...	9,554 639
1877 ...	3,808,186	1,612,182	1,320,380	1,399,273	177,139	8,317,460
1878 ...	5,501,127	2,077,962	2,174 558	2 255,090	424,678	13,032 415
1879 ...	8,257,855	2,993,584	2,085 825	2,350,837	661,676	16,352,777
	43,300,495	12,824,703	13,999,212	14,009,918	1,266,463	85,400,821
Averages	8,330,049	1,282,470	1,399,921	1,400,991	126,649	8,540,080

Average total importation 10 years 1844-53 all grain 1,052,174 hect.
" " " 10 " 1870-79 " 8,540,080 "
Total importation of grain in 1879 16,352,777 "

The above figures speak so eloquently for themselves that we need scarcely comment upon them. They supply also ample proof of the exact truth of our assertion that Antwerp has really become one of the largest corn markets of Europe. The following comparison of our last year's imports with those of Liverpool and London, undoubtedly the two largest emporiums of the European corn trade, will render that fact evident :—

Imports of Foreign Wheat in 1879.

Liverpool. London. Antwerp.
Qtrs. 3,945,721 — Qtrs. 2,855,128 — Qtrs. 2,857,380 — (hectol. 8,257·845)

This comparison shows that our imports of foreign wheat were last year fully as large as those of London and interior to those of Liverpool by only qtrs. 984 858. But this inferiority to Liverpool even is only apparent. In fact, while in England the population lives exclusively on wheaten bread, in Belgium and still more so in Germany, our principal customer, a good deal of rye is still consumed. To get a correct view of the matter, it seems to us that all grain serving for human food ought to be compared. We would then have to add to our above imports of wheat, hect. 2,993,584 —qtrs. 1,035,584 of rye, of which article the import is *nil* in Liverpool. This will make our total qtrs. 3,892,973 wheat and rye against qtrs. 3,845,721 imports of wheat into Liverpool, or a surplus of about qtrs. 50,000 in our favor. Such argument may also be justified on the ground that the substitution of wheat for rye is progressing rapidly in Germany, and the consumption of the latter grain will very likely soon become there as trifling as it is already in Belgium ; in future the imports of wheat will therefore be correspondingly increased at the expense of rye.

Our trade, as shown by our imports in the years from 1870 to 1879, and especially by those of last year, is already sufficiently important to be worth the while of shippers in all corn-growing centres to compete for a share of it But they will have the more reason for doing so, if they consider that this trade is as yet only in an early stage of its development and that it bids fair to increase still very considerably. In fact, Antwerp is not only the commercial emporium of Belgium, it is also the most favorably situated port for a large part of Germany and France. A glance at the map will show that our market extends far beyond our southern and eastern

* The Hectolitre is equivalent to 2¾ bushels.—ED., *I.A.*

frontiers and comprises large territories with dense industrious and wealthy populations which may be considered as our natural customers. No other continental port except Rotterdam, and that only as far as the navigation on the Rhine is concerned, can in those quarters compete successfully with us. What we have said in the beginning of this notice of the transformation of commerce and industry applies in every respect to these countries. Our trade with them has augmented considerably, especially since the annexation of Alsace-Lorraine to Gemany, which secured for us the cheapest, because it is the shortest. railway route to these provinces and Switzerland. The consequent accession of trade is one of the chief reasons of the enormous increase of our corn imports. (a)

That this trade will go on developing there is no doubt. The progress realised until now was obtained under a system of partial free trade. We may reasonably hope to enjoy one day the blessings of complete commercial freedom. What might then be the expasion of our trade? There is certainly every reason to believe that it would develop in a similar manner as the British corn trade has done since 1846 when the great economical reform of Sir Robert Peel was completed by the repeal of the corn laws. It may therefore be interesting to give here some statistics concerning this trade.

We extract from M'Culloch's supplemental notes to Adam Smith's "Wealth of Nations" the following table of the imports of wheat and flour of the 12 years ending 1846 :—

Imports of Wheat and Wheat Flour into the United Kingdom during each of the 12 years ending 1846.

1835 ...	Qtrs,	42,628	1839 ...	Qtrs.	2,634,556	1843 ...	Qtrs.	941,902
1836 ...	"	168,647	1840 ...	"	1,993,383	1844 ...	"	1,100,361
1837 (b)	"	455,871	1841 ..	"	2,409,754	1845(c)	"	871,256
1838 ...	"	1,241,460	1842 ...	"	2,722,349	1846(d)	"	1,436,686

The average of these 12 years is ... ... Qtrs. 1,334,904
According to the official returns the average importation of the last 15 years, 1865 to 1879, amounted to " 10,736,110
The increase has therefore been in the ratio of 1 : 8.

From a comparison of the above tables of our imports for the years of 1844 to 1853 and 1870-79, it will be observed that a similar growth has taken place in our trade.

The average of our imports in the former period was Hect. 623,356
and in the latter 4,330,049
thus an increase in the ratio of 1 : 7

If such an increase has been realised under much less favorable circumstances than those which existed in the United Kingdom, what would be our progress, if our trade were allowed to develop freely?

Every experienced merchant will perceive at once the immense margin for expansion still existing here.

There is, however; another stimulus which has come into play quite recently, and which may in the end prove more powerful than all the internal causes which favored the development of the international corn trade in the past.

A good deal of uneasiness has been created in agricultural circles by the enormous importation of foreign grain, especially from America, in 1878, in spite of the low prices then ruling. The question has been earnestly discussed since, whether the old European agricultural system will be able to stand the competition of the large, new and cheaply producing countries, foremost of which stand the United States. This competition was not very dangerous as long as the cost of transport was so heavy that only with pretty high prices ruling in Europe an extensive import from such distant countries could take place. But, now that railways have been so extensively constructed and freights have become so much reduced by the building of large sized vessels and steamers, all supplied with improved machinery, there can hardly be any doubt that whenever crops are abundant in such new countries (and they will very likely always be so in one or the other), a large supply of grain from thence may be expected even at such moderate prices as were current in 1878. It must not be lost sight of that the United States will very likely not remain the only country producing grain on an immense scale. Canada seems to have good prospects in this respect; in India and Australia the production is fast increasing, and last, not least, the River Plate States bid fair to become soon an important source of supply.

Very competent authorities in Europe (1) have contended that, unless the old European agricultural system be entirely reformed, the landed interest is threatened with complete ruin, and that protective duties, and even much higher ones than those recently introduced in Germany, would be quite unavailing to prevent this. The exclusive growing of corn is condemned, and the substitution of green crops combined with cattle breeding and the industries connected therewith, is recommended. This would imply a large reduction of the European production of grain and a corresponding increase of foreign imports.

From the foregoing we think we may safely draw the conclusion that the continental corn trade is more and more deserving the full attention of grain shippers in all parts of the world, and that of all the European continental markets, where an extensive and regular business in grain may be done, the most important is indoubtably Antwerp.

BERDOLT & Co.

Antwerp, January 1880.

(a) As long as Alsace and Lorraine were French provinces, and the railways there dependencies of the "Chemin de fer de l'Est," the French ports enjoyed tariff favors which deprived us of our natural advantages and rendered competition extremely difficult. This was changed immediately after the war.

(b) In 1837 and succeeding five years the crops were considerably deficient.

(c) First appearance of the potato disease.

(d) The worst crop on record.

UTILIZATION OF CITY REFUSE AS MANURE.

No. 1 51, dated Poona, the 31st March 1880.

MEMORANDUM—By J. H. E. HART, Esq., C.E., Superintending Engineer for Irrigation.

Submitted for the information of Government in the Public Works Department, Irrigation, with a copy of this office No. 5026, dated 12th November 1879, and Government Resolution No. 3222, dated 29th November 1879 (General Department).

2. The Superintending Engineer for Irrigation is induced to draw the special attention of Government in the Irrigation Department to the importance of the information furnished in these reports by the officers of the Poona Municipality on the subject of the use of poudrette as a manure.

3. The précis of correspondence, circulated under Government Memorandum (General Department) No. 2633, dated 31st August 1875, shows that the use of poudrette was up to that time almost entirely unknown in this presidency, except on a restricted scale in a few places.

4. The development of the revenue realised by the Poona Municipality from the sale of poudrette, since the opening of the Mutha Canals, is of great importance. The manure supplies a want essential to any great extension of garden cultivation, and the revenue realised by the Municipality is so considerable that it may fairly be hoped other Municipalities will make some endeavour to turn to account the sewage of their towns, more especially in places like Sholapur, Karar, Satara, &c., situated in the vicinity of large irrigation works. It is believed that at the instigation of Mr. Burke, the manufacture and sale of poudrette has been taken in hand by the Sholapur Municipality within the last few years, and with satisfactory results. Detailed reports on the subject might be asked for.

5. It appears from the papers that originally a system of preparing the poudrette by heating the night-soil in furnaces was experimentally tried at Poona, but was subsequently abandoned as being too elaborate. The "sun-drying" process was then resorted to, and the result is approved both by sanitary and medical officers and by the purchasers. It may be noted that this process is almost exactly that described as followed in Nasik *vide* the précis referred to in paragraph 3.

6. The following are some of the most important matters on which information is obtainable in connection with the manufacture and sale of poudrette in Poona :—

Population of city 90,436.

Night-soil 44 cart-loads=575 cubic feet per day. This shrinks in drying to 430 cubit feet.

Street sweepings 65 to 75 cart-loads=1,950 cubit feet per day. When burnt and sifted produce is 300 cubic feet of ashes.

Poudrette 436 cubic feet of night-soil mixed with 300 cubic feet of ashes produce 730 cubic feet of poudrette per day or 266,150 cubic feet per annum.

The price realised is Re 1 per cubic yard or 27 cubic feet. The annual value of the poudrette is thus Rs. 9,8[illegible]0 at current rates. This is incorrectly stated by the Secretary, Poona Municipal Committee, as Rs. 4,984.

The cost of conveying night-soil and sweepings to the depôt is shown as Rs. 11,736. The cost of manufacturing the poudrette is stated as Rs. 6,264. The cost of convoyance has of course to be incurred in any case. The manufacture of the poudrette will yield a very handsome profit to the Municipality. The Municipal Secretary notes that the price of the manure is susceptible of increase, and the cost of manufacture of reduction.

The revenue from the sale has increased from Rs. 766 in 1874-75 to Rs. 7,438 during the first 9 months of the current year (1879-80).

7. The remarks in paragraph 10 of the Secretary's letter are worthy of particular attention. He states that 5 years ago cultivators "would not touch the poudrette" and "could not be induced to take it away at even a nominal charge. At the present moment the outturn of manure is not enough to keep pace with the demand, and it has become necessary to take special precautions that the poudrette is not taken away in its raw state which the cultivators sometimes attempt to do. They frequently pay for manure to the Municipality from 4 to 6 months *in advance* in order to ensure a timely supply."

8. The Superintending Engineer recommends that Mr Plunkett's letter and the report by Mr. Narso Ramchandra, Secretary, Poona Municipal Committee, be printed and copies circulated to all Presidents of Municipalities and to Cantonment Committees. Also that the papers be printed in the *Government Gazette*. Copies might also be furnished to the Government

of India, *vide* Government Resolution (General Department) No. 850 of 23rd March 1880 and to the Inspector-General of Prisons.

No. 98, dated Poona Municipal Office, the 14th January 1880.

From A. H. PLUNKETT, Esq., City Magistrate and Chairman, Poona Municipality, to the Collector, and President, Poona Municipality.

With reference to Government Resolution No. 8223 of the 20th of November last, in the General Department, I have the honor to report that the following sums were realised by the sale of poudrette manufactured by the Poona Municipality during the past five years :—

YEAR.	Approximate quantity manufactured in cubic feet.	Amount realised in Rupees.	REMARKS.
1874-75	60,000	766	All sold during the year.
1875-76	90,000	1,308	
1876-77	120,000	2,632	
1877-78	150,000	2,840	About 2,500 cubic feet remained unsold.
1878-79	220,000	4,356	About 100,000 cubic feet remained unsold. The selling price was increased 50 per cent.
1879-80 (up to 1st January 1880, 9 months.)	200,000	7,438	About Rs. 2,300 were obtained from the sale of old stock.

2. The mode of preparing the poudrette advocated by Rao Bahadour, Professor Keru Luxman Chatre in his report (copy of which is appended for ready reference).* was abandoned as too elaborate and expensive after a very short trial. The mode now adopted is described in the accompanying report of the Municipal Secretary.

* Not printed.

3. I beg to remark that the present mode of preparing the poudrette has the approval of the medical profession and the Sanitary Commissioner of Bombay, and to add that the value of the poudrette as a manure is recognized by the agricultural classes, the demand for it being steadily on the increase since the opening of the Mutha Canals.

Report on the disposal of the night soil of the City of Poona and its Preparation into Poudrette.

The process adopted may be called the "sun-drying process." It consists in exposing night-soil in shallow beds covered with ashes to the sun to dry, and,when perfectly, dried in heaping it away to be sold to agricu turists for manure.

Night-soil.

2. About forty-four cart-loads of night-soil are daily collected in the city, and carted out to a depôt at the village of Dhankodi, 2½ miles away to the south of the city from its extreme limits. Twenty-two carts each of a capacity of 18 cubic feet are employed. They make two trips a day. They are barrel-shaped (5′ 9″ long and 2 diameter) and are perfectly air-tight. They have a mouth for filling on the top at the fore end covered with an air-tight trap lid and an opening at the left end at bottom for emptying, covered by a close fitting short piston, which is worked up, and down by a screw worked from the top of the cart.

3. The carts are taken away three-fourths full, each containing about thirteen cubic feet of matt er. The space left vacant is required partly for the location of the gas which is generated in the night-soil when exposed to the sun and stirred by the joltin g of the carts, and partly for preventing the night-soil from spilling or overflowing as it rises while fermenting and while the gas is produced.

4. The night-soil collecte d is in a semi-liquid state, as a great quantity of water used by people for ablution mixes with it, from which it cannot be separated. About 575 cubic feet of such soil is collected daily.

Ashes.

5. Street and house swee pings collected from the dust-bins of the city are carted out and burnt into ashes, which are afterwards carted out to the depôt referred to in paragraph 2 above. The carts are of open box form, 5 feet long, 8 feet broad, and 2 feet deep, which make a capacity of 30 cubic feet, 25 carts are employed, and they make three trips daily. Allowing for stoppages, accidents, &c., about 65 cart-loads of sweepings, consisting of house ashes, stable litter, sweepings, and a quantity of road dust and brickbats are taken out daily. The total refuse thus taken out is about 1,950 cubic feet. When burnt, it is reduced to 2/13ths of its bulk, or about 300 cubic feet of pure ashes.

Deodorisation.

6. At the depôt, beds are formed with a floor made of moorum or other hard substance to receive the night-soil ; the beds are 18 feet square and 1 foot deep. A layer of ashes one inch thick is first spread over the floor of the beds ; night-soil is then poured on, about 5 inches deep, and is covered over with a layer of ashes also an inch deep. It is then allowed to remain for 24 hours in the sun during the fair season and for three days under sheds during the rainy season. The night-soil is, after the lapse of the time mentioned above, stirred and well mixed with the ashes spread above and below it, and a fresh layer of the latter, ½ inch thick, put on, when it is allowed to lie for three days further in the fair season and eight days during the rains. The mixture is then again stirred, taken out of the beds, and spread on dry open ground exposed to the sun to complete its drying. It is then stored in heaps for sale, and is in dry weather fit for immediate use.

7. In the rainy season the drying has occasionally to be done under cover, and consequently the process occupies as many as 12 days, whereas in the cold season it takes six days, and in the hot season only four days.

Remarks.

8. Experience has shown that ashes form the most efficient and cheapest deodoriser of the noxious gases generated from night-soil, and the depôt when there is no uncovered night-soil in it, is free from stinks at a distance of 50 yards on its windward, and not more than 150 yards on its lee-ward side, provided always that the supply and use of ashes is sufficient.

9. It will be observed that 575 cubic feet of semi-liquid night-soil is obtained daily from the city, and only 300 cubic feet of ashes, that is, the latter is a little over one-half of the former. Experience has shown that to ensure thorough deodorisation, complete freedom from stink, and the best poudrette, the proportion of ashes to night-soil should be about equal, and the Municipality are trying to augment their collection of ashes to the required quantity.

Poudrette.

10. The manure prepared in this manner is much valued by cultivators, and is in great demand. Applications for the manure have been increasing since the opening of the Mutha Canals, and consequent extension of wet cultivation. Five years ago, agriculturists would not touch the poudrette thus prepared, and could not be induced to take it away at even a nominal charge. At the present moment the outturn of manure is not enough to keep pace with the demand, and it has become necessary to take special precautions that the poudrette is not taken away in its raw state, which the cultivators sometimes attempt to do. They frequently pay for manure to the Municipality from four to six months *in advance*, in order to ensure a timely supply.

11. The poudrette manufactured by the Municipality is clean and free from brickbats, broken glass, and other rubbish or common earth. This is secured by the ashes being sifted before being mixed with night-soil.

12. It may not be out of place here to quote a paragraph from a letter, No. 618 T, dated 8th November 1879, from the Sanitary Commissioner of Bombay, on the mode of prepar ng the poudrette now followed by the Poona Municipalitiy :—

"Before the depôt is removed it is only fair to place on record that hitherto its management reflects the highest credit on all concerned. I have visited it often and unexpectedly, and remembering how rude are the means as they generally are in India, I can answer for it that every process is very carefully conducted."

Quantity manufactured.

13. Five hundred and seventy-five cubic feet of semi-liquid night-soil and 300 cubic feet of ashes are collected daily at the depôt and mixed together. The night-soil shrinks in drying to ¾ths its bulk or about 430 cubic feet. The daily outturn of poudrette is therefore 430 + 300 = 730 cubic feet, or 266,450 cubic feet in the year.

Financial results.

14. Before concluding this report, it will be of interest to note the financial results of this branch of work of the Poona Municipality—

	Rs.
44 cart-loads of night-soil conveyed daily to the depôt by 22 pairs of bullocks at Rs. 24 per pair with driver per month, cost per annum	6,336
65 to 75 cart-loads of street sweepings conveyed daily to the depôt by 25 pairs of bullocks at Rs. 18 per pair with driver per month, cost per annum	5,400
Cost of sifting refuse, burning, preparing ashes, mixing night-soil and preparing poudrette, per annum	2,064
Maintenance of sheds and beds at the depôt, per annum ...	900
Repairs to night-soil and refuse carts, per annum	2,500
Tools, plant, and contingencies	200
Total cost per annum Rs. ...	18,000

15. The poudrette is now sold at 27 cubic feet, form ng 96 ordinary iron baskets full for a rupee ; the annual revenue from the 266,450 cubic feet of poudrette prepared is Rs. 4,934, say 5,000.

16. There is thus at the present moment a net loss to the Municipality of Rs. 13,000 per annum. It should be borne in mind that the Municipality would have as its first duty to remove the night-soil and refuse of the city in some way or other ; what therefore has been mentioned as a net loss to the Municipality is only what it costs them to get rid of the filth of the city in the best manner possible. The price of poudrette is yet susceptible of increase and the cost of preparing it of decrease, and it is possible that the cost to the Municipality might be reduced in three or four years to Rs. 7,500, only by reducing charges from 18,000 to 15,000, and increasing sale proceeds of poudrette to Rs. 7,500. The sale of poudrette will thus pay half the cost of the removal from the city of its night-soil and street and house sweepings.

NARSO RAMCHANDRA,
Secretary, Poona Municipal Committee.

SELECTIONS.

THE LATE ROBERT FORTUNE.

ONE OF THE FATHERS OF THE INDIAN TEA INDUSTRY.

MR. ROBERT FORTUNE who took a large share in the cultivation of tea in the Himalayas, and introduced a very large number of useful and ornamental plants, died on April 13th last. He was a botanical collector of no ordinary merit. He was born in Berwickshire on September 16, 1812, and was educated in the parish school of Edrom. Showing an early preference for gardening, Fortune served his apprenticeship in the gardens of Kelloe, the residence of Mr. Buchan, whence he went to Moredun, near Edinburgh, and after some time he entered the Botanic Gardens, Edinburgh, under the elder MacNab. Here he remained between two and three years, and in 1842 he left that city and came to London, being appointed Superintendent of the Hot-House Department of the Royal Horticultural Society, at Chiswick, an appointment he vacated on being commissioned in February 1843, by the Society, to proceed to China to collect plants. In July of that year he arrived in China, and at once began that career of collecting which afterwards proved so fruitful. In that year began his communications to the *Gardeners' Chronicle* which, together with his official report in the *Journal of the Horticultural Society*, formed the basis of the books by which he is best known to the general public. Touching at Java on his outward voyage he collected a fine variety of Dendrobium secundum, which was afterwards sent home, and specimens distributed among the Fellows. A fortnight later he was at Macao, and thence proceeded to Hong-Kong. During his stay in this island he collected Chirita sinensis, Spathoglottis Fortunei, Habenaria Susannæ, Arundina chinensis, Mussaendas, and other plants. Finding, however, that Hong-Kong and the Southern districts of China had been already ransacked, so that there was little hope of getting novelties, Fortune proceeded in the autumn of this year northward, to Amoy which district he found more barren than that around Canton. In consequence he proceeded again northward by sea, narrowly escaping shipwreck on two occasions in the Formosa Channel. Compelled to refit, Fortune availed himself of the delay to explore the country around Chimoo and Chinchew, where, in spite of the hostility of the natives, he collected some attractive plants. After some time he arrived at Chusan. He availed himself of an opportunity of visiting Shanghai, at that time closed to Europeans, and explored the rich plains of the Yang-tse Kiang, where, although the cultivated state of the country was generally unfavourable for botanizing, he was fortunate enough to procure, and ultimately send home Cryptomeria japonica and Anemone japonica as well as many Chrysanthemums and Tree Pæonies. He returned to Hong-Kong early in 1844, and occupied himself in packing his treasures and in transmitting them to England. At the end of March he proceeded northward again, and was once more struck with the gorgeous beauty of the Azalea-clad mountains of Chusan, with Daphnes, Wistarias, Weigelas, Bamboos, and various other plants of great beauty and interest. At this time he visited the tea-growing district of Ningpo—his first introduction to a department in which he was destined to reap so much honor to himself, so much advantage to his country. Here he discovered in a garden the beautiful double yellow rose which bears his name, and a curious sporting variety interesting in relation to the controversy as to the rose called Beauty of Glasenwood. Of this sporting rose, Fortune says: "Sometimes it produces self-coloured blooms being either red or French-white, and frequently having flowers of both on one plant at the same time —while, at others, the flowers are striped with the colours already mentioned." In the autumn of this year he returned once more to Hong-Kong to pack and despatch the plants he had collected.

In January 1845, as it was still winter in the Northern Provinces, he sailed for Manilla, the general vegetation of which he states to be similar to that of Java. Here he collected a quantity of the lovely Phalænopsis amabilis, including one plant "with ten or twelve branching flower-stalks upon it and upwards of a hundred flowers in full bloom." In March he left Manilla for Northern China once more. During the summer of this year he visited Foo-chow-foo, and the black tea districts in the Fokien province. On the voyage from Foo-chow-foo to Ningpo, the Chinese boat in which he was, was attacked by pirates on two different occasions, and, had he not been well armed, he must have fallen into their hands. On arrival at Chusan he was suffering from fever, but managed to proceed to Shanghai where, in addition to the plants he had collected in the various districts in China, he had managed to get sundry importations from Japan, and brought the whole once more to Hong-Kong. Thence he despatched half his collection, taking with him to Canton the other half. Leaving Canton at the end of December 1845, he arrived in England in 1846. On one of his visits to Hong-Kong the Governor availed himself of his services in replanting the bare hillsides of the island. His adventures, as stated in "Men of the Time," were full of romance; and whether feasting with Mandarins, enjoying the hospitality of Buddhist priests, battling with the swarming natives, fighting single handed with pirates, or gaining admission to the city of Loo-Chow in the disguise of a Chinaman, he seems to have exercised equal energy and sagacity."

The results of this journey were summarised in his "Three Years Wanderings in the Northern Provinces of China," published in 1847 Chinese gardening and agriculture of course took up a principal portion of the book, and in particular the history of tea culture was made known, Fortune having had the rare opportunity of dwelling in a monastery or temple in the heart of the tea districts. The whole process of manufacture was examined by him, and the important fact made known that black and green teas are both produced from the same plant—in the northern districts from Thea viridis, and in the southern from Thea Bohea—the difference in their quality depending entirely upon the manner of preparation. In this volume we find accounts of the mode of dwarfing trees, and of their system of gardening their glorious Azaleas, their many coloured Chrysanthemums, their noble Pæonies. A second edition of this volume was soon called for.

Shortly after his return to this country he was appointed, in 1846, on the recommendation of Lindley, to the Curatorship of the Botanic Garden of the Society of Apothecaries at Chelsea, and during his tenure of office set himself to work to reform that establishment. Two new houses were built, and heated on the Polmaise system, which was soon abandoned.

In May 1848, at the instigation of the late Dr. Royle, Fortune was commissioned by the East India Company to proceed to China again, and to collect tea seeds and tea plants for transmission to India. He applied for two years' leave of absence to the Apothecaries' Society, but as this could not be consistently granted, Fortune resigned his appointment, amid expressions of regret and good will on the part of his employers, and proceeded once more to China.

In 1849 we read of his success in collecting tea plants, and in 1850 he communicated to our columns his discovery of a primrose-yellow Camellia, and his description of the graceful Cupressus funebris. Several of the plants collected in this journey were transmitted to Mr. Standish for distribution.

In 1851 he arrived in Calcutta with nearly 2,000 young tea plants and 17,000 germinating seeds; with these he proceeded to the North-West Provinces of India, where he served to lay the foundation of the Indian tea industry.

In 1852 he paid a second visit to China, in the service of the East India Company.

In 1857 appeared another work from Fortune's pen, entitled "A Residence among the Chinese, Inland, on the Coast, and at Sea." Here we have a *resumé* of his travels in the tea districts of Chekiang (second visit Shanghai, Canton, Foo-chow-foo, and Formosa. Subsequently he visited the cooler districts of China, including the silk districts, where he carefully observed the whole process of silk manufacture. The book goes on to record his second journey to India and his return to England.

In 1858 he again proceeded to China, in the service of the American Government, and in 1859 he was awarded a medal by the Paris *Société d'Acclimation*, in acknowledgment of the number and value of his introductions.

In 1862 Fortune returned from Japan and Northern China, bringing with him various specimens, amongst other things an Artemesia used as a stock by the Chinese whereon to graft the Chrysanthemums as standards.

In the following year (1863) appeared a book descriptive of this his fourth and last journey to Japan and China, under the title of "Yedd and Peking; a Narrative of a Journey to the Capitals of Japan and China, with notices of the Natural Productions, Agriculture, Horticulture, and Trade of those Countries, and other things met with by the Way."

Thus ended the wanderings of this keen botanist and most persevering collector.

Mr. Fortune formed one of the Committee of the International Exhibition, 1866, but from that time gradually retired from horticultural pursuits, and betook himself to farming in Scotland.—*Home & Colonial Mail.*

THE OPIUM TRAFFIC OF ASIA.

IN a review of the British Opium trade in India and China, Professor Christlieb, of Bonn, gives the following statistics showing the magnitude of the trade, and its effects upon Indian agriculture.

Since the conclusion of the Treaty of Tientsin, in 1860, the quantity of opium imported into China from the East Indies has increased to 80,000 chests. In 1875 as many as 85,454 chests, worth £10,000,000, were brought into the Chinese market, 8,943 of which were sent to Malacca, while the consumption of the drug for medicinal purposes in Great Britain in the same year reached only 165 chests. The progressive growth of the trade during the past 80 years is thus shown. In the year 1800, about 5,000 chests; in 1825, 12,000 in 1850, 50,000, and in 1875, 90,000. Among the most striking effects caused by the expansion of poppy plantations in India are the diminution of the quantity of land available for other crops, and the consequent curtailment of food products. In Benares and Behar, immense tracts of the finest and most fertile land in Northern and Central India have been gradually covered with poppy plantations. Quite recently 100,000 acres of the richest plains in Central India, and 55,000 acres in the valley of the Ganges which formerly used to produce corn, sugar, and indigo, have, to the impoverishment of the soil, been devoted to opium culture. The acreage devoted to that purpose to-day is estimated at 1,033,000 acres.

Apropos of the drug, Mr. Arthur Pease expressed his intention some little time ago of bringing the opium question in its relation to China before Parliament. We presume the telegram respecting the discussion which took place on the 5th instant had reference to Mr. Pease's motion, and it does not seem that the opponents of the traffic have gained much thereby. On the other hand, the Society for the suppression of the Opium Trade is

actively at work now that a Liberal Government is in office. We see that the last annual meeting was very influentially attended; but the newspapers were incorrect in stating that the Chinese Ambassador was present. His Excellency, though sympathising with the object of the meeting, rightly deemed that his official position precluded the possibility of his attendance. The annual report of the Society was, it must be confessed, drawn up in a spirit of thankfulness for small mercies. As to our own Government "there was no improvement to announce;" as to India "there was nothing good to report;" as to China "there was singular indifference." Moreover "there had been a marked increase in the opium trade." Nevertheless "the labours of the Society have been cheered by evident signs of awakening interest," and consequently it was hoped that "friends would assist the Society with funds so as to spare the committee the necessity of a second special appeal." The speeches, which were most warmly applauded, were of the usual calm and judicious character. The Earl of Shaftesbury prophesied that if this national sin were not done away with, Divine vengeance would assuredly afflict England and India. The resolutions declared that it was the opinion of the meeting that the support of the opium trade by the British Government is immoral and unjust—'immoral, inasmuch as the Indian Government does not confine itself to 'taxing a deleterious article, with the intention thereby of diminishing its consumption, but directly promotes the manufacture and sale of opium for the sake of gain, although cognisant of the injury thereby inflicted upon China, and in a less degree upon its own subjects in Burmah and elsewhere; unjust, because the British Government prevents China from defending herself in her own way against the introduction of a demoralizing drug." Further, "opium being recognised and declared by Act of Parliament to be a poison, the Indian Government ought at once, without rescinding its existing law against the production of opium by unlicensed individuals, to cease from in any way promoting or encouraging its cultivation for other than medicinal purposes; also, that the Chinese Government ought to be left entirely free to act as it pleases in reference to taxing opium, or altogether prohibiting its introduction in China."—*Lucknow Times.*

ON LOSS OF NITROGEN IN LAND.

DR. J. B. LAWES, F.R.S., writing to us from Rothamsted on the 15th instant, says:—

Your correspondent, Mr. Melvin, asks for further information respecting the loss of soluble nitrogen. We have in our possession a great number of analyses of the drainage waters from the variously manured experiments in our permanent wheat field, and also from an unmanured and an uncropped soil, and we hope to write fully on the subject before the end of the present year. In the meantime, the few observations which I am about to make, may possibly be interesting to your readers, and also, to a certain extent, supply some illustration of the subject with regard to which Mr. Melvin is anxious for further information.

So long as agriculture depended upon the nitrogen stored up in the soil or that obtained from the atmosphere, the loss of this substance was comparatively unimportant. When, however, nitrogen is placed upon the land at a cost of something like one shilling per lb., the whole question relating to it assumes an importance second to none in practical agriculture.

Before I enter upon the subject of nitrogen, I must first make a few remarks upon the distinction between natural vegetation and agriculture.

There is no doubt but that a most luxuriant vegetation may exist in connection with an enormous rainfall, provided there is at the same time a sufficiently high temperature; but this vegetation is perennial; the roots have complete possession of the soil, and can take up their food, if not during the whole, at all events during the greater part of the year.

When annual crops are grown in tropical climates, or even in climates which, although not tropical, have a rainfall and summer temperature much higher than our own, we do not find great luxuriance of growth; in India for instance, the average yield of wheat is 10 bushels per acre, and in the United States it only amounts to about 12 or 13 bushels.

Agriculture differs from natural vegetation in two very important characteristics—(1) it substitutes annual for perennial vegetation; (2) by constant stirring of the soil it liberates and makes use of the fertility stored up by previous generations of plants; but when the nitrogen obtained from these sources is not sufficient to grow the crops required, a further supply from other sources must be brought upon the land.

Vegetation takes up, and converts into organic compounds, the salts of nitric acid; but in the absence of vegetation, we have reason to believe that with sufficient rain, it is entirely washed from the soil.

There is not a single operation in agriculture which is not, more or less, connected with the liberation of nitrogen from some insoluble compound, or the reconstruction of the soluble nitrogen into living vegetation; and the process of liming, of fallows, and of rotation of crops, must all be studied in connection with the properties of nitrogen before any clear comprehension of the subject can be arrived at.

Perennial vegetation, such as exists for instance in a permanent pasture, would therefore waste less nitrogen than any rotation of crops, and the nearer the rotation approached to a perennial character, the less would be the loss of nitrogen. Assuming that the purchased nitrogen always suffers more or less loss and that the ultimate amount of such loss is closely connected with the character of the crops grown, it is obvious that the selection of the manure suited to the particular crop, and also the choice of the time most suitable for its application, must have a great influence on the result.

I have hitherto dwelt upon the loss of nitric acid incurred by drainage; there is however, another source of loss, which, though not so obvious, cannot be ignored in practice. I allude to the fixation of ammonia by the soil. When salts of ammonia, or any manure containing ammonia, is placed on the land, it unites with the soil, and, provided that the moisture in the soil is favourable, the ammonia, by the action of a minute underground vegetation, is converted into nitric acid, in which form it is taken up by the growing crop.

For some years we have had parallel experiments going on in our wheat fields; in one, the salts of ammonia are applied in the autumn; in the other, they are applied in the spring. In 1874, when both the winter and spring were dry, the wheat crop was considerably larger with the autumn than with the spring sown ammonia, one being 39, and the other 29 bushels; and from certain indications I am by no means sure that the same result may not occur during the present year.

Between the time of sowing the spring manure in 1874 and the end of June, five inches of rain fell, so that the spring sown ammonia had abundance of water to dissolve it, and yet from the result, as shown in the crop, its full action was not available. We have here evidence that the crop may suffer from want of activity just as it may from too much activity in the nitrogen.

In farmyard manure, we have no nitric acid, only small quantities of ammonia, but a large proportion of organic matter which yields ammonia by decomposition. As, however, the action, and the ultimate exhaustion of farmyard manure, extends far beyond the period generally assigned, there is very great difficulty in measuring the loss of nitrogen that actually takes place.

At present we have no evidence derived from our experiments to show that the loss of nitrogen in nitrate of soda is greater than it is in any other form in which nitrogen, is applied to the soil.

Mr. Melvin in his letter of April 26th, remarks that there was no want of straw in the Lothians, in the wet, cold years of 1877 and 1879, but a want of power or force in the life of the plants fully to develop the grain.

It would appear that a certain, but a different amount of temperature is necessary to produce the same substance in different plants. For example, the cereal grains all produce starch; but rice and maize will not thrive in England, nor will wheat thrive so well in Scotland as in the English southern counties, and the same may be said of mangels. While, therefore, a certain amount of heat is essential to ripen a crop, we do not know how far the loss of nitrogen, due to previous rains, may have influenced the amount of yield.

The facts I am about to relate will serve to illustrate my meaning.

In 1878 the highest produce of our permanent wheat field was 38 bushels of corn, and nearly 3 tons of straw per acre. In an adjoining field of 18 acres, the same variety of wheat, sown almost the same day, gave 59 bushels per acre, or an excess of 21 bushels over the experimental crop, but the straw in both crops was equal. There was no probability of a mistake about either produce; and, further, in the same field of 18 acres, about 20 varieties of wheat were grown, some of which yielded considerably more than 19 bushels, while the whole produce of the field, which was thrashed and weighed, reached the amount of 60 bushels per acre.

At the first sight, those facts seem very hard to reconcile; but when we come to examine the circumstances under which these two crops were grown and the character of the season, we shall be able to form some judgment regarding the great difference in the produce.

The experimental wheat received every year alcaline salts, phosphates, and more nitrogen, in the form of salts of ammonia or nitrate of soda, than the largest possible crop of wheat contains; but all the produce (above 12 to 15 bushels grown by the minerals alone) is entirely due to the soluble nitrogen. Now, the adjoining field of 18 acres, where the varieties were grown, had received in 1877 a heavy application of farmyard manure for a crop of mangels; but the land not being ready in time, white turnips were sown in their place, and the crop, which was small, was carted off. In the autumn, wheat was sown which the following spring received a top-dressing of 2 cwt. of nitrate of soda. The ammonia and nitrate in the experimental field, and the nitrate of soda in the other, were both sown in the month of March; and, between that month and the end of June, nearly 12½ inches of rain fell, six of which passed through five feet of soil, and were collected in a guage placed at that depth for the purpose.

During the month of July the weather was brilliantly fine; and the straw, although over six feet in height, stood perfectly upright at the time of harvest.

Now it is quite evident that a great deal of nitric acid was washed out of both fields; but while the wheat in the experimental field depended entirely on the soluble salts, the wheat in the 18-acre field could fall back upon the store yielded by the nitrogen contained in the farmyard manure.

In the experimental field there appeared on the wheat from day to day at the time of blooming, a quantity of small black flies, and the eggs laid by them ultimately produced maggots, which fed upon the young grain. They also appeared on the wheat in the 18-acre field, but did not multiply there. At a certain critical point in its life the experimental wheat showed a want of vigour and health, which ended in a yield of straw out of all proportion to the grain; while in the 18-acre field the crop, as regards the yield both of grain and straw, was one of the largest ever grown upon the farm.

With a summer competent to produce so large a crop, we must seek for some cause to account for the general produce of the country being but little over the average; and I think we cannot be wrong in assuming that the washing away of the nitric acid by the great rainfall in the spring and early summer may have been one of the causes which produced this result.

In my previous communication I pointed out why I considered that the improvement of the Highlands should take the form of pasture rather than that of arable land. Even where the rainfall is not greater than it is in the south of England, the atmosphere in Scotland is far moister, and I should expect to find that more drainage would take place there for an equal fall of rain.

In Scotland about 40 per cent. of the arable land is under a rotation of grasses; while in some of the southern counties of England this system of cropping does not exceed 10 per cent.

If the results obtained at Rothamsted with regard to the loss of nitric acid have a general application, it must be evident that where a rotation of grasses occupy 40 per cent. of the arable land, the loss of nitric acid must be very much less than where it occupies only 16 per cent.

It would appear as if the selection of the special form of nitrogen to be used should have some reference to the character of the crops to be grown.

For instance, if seeds were sown with the corn, and an application of salts of ammonia, or ammonial guano, failed to produce its full action upon the grain from the weather being too dry, there would be the comfort of knowing that later in the season the seeds would take up the residue.

If, on the other hand, a grain crop alone was to be taken, or ryegrass, for hay, was required, an application of the more active nitrate of soda might probably produce a better result.

Upon my own farm I have always obtained better crops from nitrate of soda than from ammonia in any form; but the recent high price of nitrate has caused me to use soot for my wheat, and guano containing 10 per cent. of ammonia for my spring corn and roots; with what result remains yet to be seen.—*North British Agriculturist.*

CULTIVATION OF THE COCOANUT.

MR. G. E. LAYTON, Secretary of the Queensland Commission of the International Exhibition, has kindly forwarded to us (*Sydney Mail*) the following interesting paper on the "Cocoanut Palm" by Mr. Walter Hill, Director of the Brisbane Botanic Garden:—

I have elsewhere referred to the fact that there is a natural growth of cocoanut trees on some of the islands, on the north-east coast of Queensland. From Fraser's Island North, nuts are found on the shore that have floated from some island of the Pacific, but generally they are in a decomposing state, beyond the possibility of germinating. On our coast islands the palms are not sufficiently numerous to lead to the supposition that they are indigenous, and they are probably derived from nuts carried from the distant place where they grew by the action of currents and assisted at one time of the year by the wind.

When I accompanied the N.-E. Coast expedition in 1873, I planted cocoanuts on several of the Islands we touched at, and have since sent others to be planted on Islands where there are light houses, or otherwise people residing on them. There is no doubt, but that the palm will grow anywhere to the north of Rockhampton. It is to be found so far as eighteen miles back from Keppel Bay. Plantations were successfully formed at Bowen, and afterwards at Mackay.

I do not think it probable that in Queensland, at least, regular plantations of cocoanut palms will be found anywhere than at the sea-side. It is stated that in the West Indies and elsewhere, the tree grows better and yields a larger produce when brought under cultivation in a rich soil, moist and yet naturally or artificially drained. But, in addition to the increased trouble and expense, the crop and the trees in an inland plantation are more liable to the attacks of insects, and of larger animals, than when the palm grows on the edge of a sandy shore, exposed to the wind and sometimes drenched with the sea spray. In some countries within the tropics, cocoanuts are grown in mangrove soil on the banks of salt water creeks, and, although the milk is brackish, yet they yield as much oil as those grown in sandy soil, and the tree bears sooner. The only cultivation required under such circumstances is to cut drains, so that the tide can flow in and out and, as stagnant water, lodge at the roots. It is said that the tide is found to deposit amongst the trees a very fertilizing matter.

There are at least thirty known varieties of the cocoanut. The one that I think will be best suited for this colony is a small kind, indigenous to the Maldive Islands, and much valued in Ceylon. A few years ago, in the latter island, there were 200,000 acres of land devoted to the growth of cocoanuts, the annual return from which was two millions sterling, including exports, and the estimated value of home consumption.

The average produce of a tree may be put down at 100 nuts per annum. In Jamaica, under favourable circumstances, the yield is double that number. Forty nuts yield a gallon of oil—of course, when small, the quantity is not so great, but this is made up by the trees producing a greater number of small nuts. The trees live for a century—it is under the average to state that they bear for forty years, taking into consideration the number of those in cultivated plantations which cease to yield at an early period through the ravages of insects, plant diseases, &c.

I do not anticipate that at present, where there are so many other openings for the profitable employment of capital, the formation of plantations and the preparation of oil and coir will be entered into unless on a small experimental scale. But every one who owns or occupies land on the islands or shores of our Northern coasts, could derive a good addition to his income by planting cocoanuts in the otherwise waste and useless land along the seaside, and disposing of the "copra," or dried kernel of the nut, of which although an immense quantity is exported from the Pacific Islands and elsewhere, the demand is practically unlimited. The "copra" contains from 50 to 60 per cent. of oil. It is cut up fine, steamed, and the oil expressed from the pulp by a powerful hydraulic press. The resulting oil-cake is used to fatten cattle, fowls, &c., and all animals eat it eagerly.

I have generally supplied the commanders of the surveying schooners with cocoanuts, yams, sweet potatoes, &c., to be planted on the islands at which they touched. I have done so invariably when I received notice of the time of departure of the vessel. It is probable that the beginning of a cocoanut plantation may be found on some of those islands. It will be a great pleasure for me, as well as a duty, to assist in promoting the success of such an enterprise.

W. H.

WILL COTTON CAKE, GIVEN TO THE COW, IMPROVE THE QUALITY OF THE MILK?

I PROPOSE to give my dairy cows 3 or 4 lbs. daily of decorticated cotton cake, while upon the grass. My object, of course is to increase the quantity of butter; but would this feeling not also have the effect of leaving so large an amount of flesh-formers and phosphates of lime in the skim-milk as greatly to increase its feeding value for the calves, and so obviate the necessity of adding any feeding stuffs to the milk?—R. C.—[Three or four pounds of cotton cake will certainly prove of much service to your cows, especially whilst these ungenial east winds interfere so seriously with the growth of grass, and, indeed, with vegetation generally. It will add alike to the quantity and quality of the milk; it will raise its standard of nutritive value, but not to such an extent as to persuade the calves fed on the skim-milk to thrive, as you hint, as if they were receiving new milk. The larger amount of cream from rich milk, moreover, rises faster, than it does from poor milk; so that whilst with the use of cotton cake you would have more butter, your calves would not have any increased amount of the oleaginous elements which are so essential for their growth, and which, in an artificial dietary, consisting mainly of skim-milk, has to be made up to them by the addition of boiled linseed, of finely crushed linseed cake, or of such wholesome saccharine materials as treacle and locust beans. The percentage of flesh-formers and phosphates in the skim-milk, as ingeniously suggested, would certainly be somewhat increased by the cotton cake, but the increase would not justify the attempt to bring up the calves without oatmeal or other such helps. Even with the best of food given to cow, it is difficult to raise the nutrient value of milk beyond the normal standard. Excess of the elements of nutrition are not concentrated in the milk, but rather go to add to the weight of the cow's own body, or increase somewhat the proportion of waste materials. Besides the good purposes named, decorticated cotton cake, as you are aware, contains a large proportion of albumenoids, which, under ordinary circumstances, are not assimilated by animals; and, hence, about one-third of the cost price of the cake may be credited to the value of the manure heap.—VET. ED.]—*N. B. Agri*:

SWALLOWS AS FARMERS' FRIENDS.

A WELL-KNOWN naturalist, M. Florent-Prevort, who has been engaged for a series of years in making observations on the contents of the stomachs of various insectivorous birds, recently communicated to the French Senate the following interesting details in the food of swallows. He examined with the utmost care the stomach-contents of eighteen of these, which he captured for that purpose, at different periods of the season, with the results here appended. In the stomach of a swallow killed on April 15 he found 422 insects; April 19, 649 insects; April 27, 301 insects; May 1, 704 insects: May 4, 660 insects; May 18, 680 insects; May 29, 300 insects; June 3, 420 insects; June 14, 244 insects; June 28, 400 insects; July 11, 420 insects; July 20, 501 insects; July 24, 500 insects; August 5, 742 insects; August 19, 690 insects; and August 29, 384 insects. The eighteen birds together, therefore, devoured no less than 8,390 insects, which were recovered undigested or at the rate of 466 each per diem; and it must be remembered that these probably represent but a small portion of the total number they had eaten during the day. When we reflect that among all this mass of indigested insects there was not a single grain of corn, or the least particle of fruit, or a trace of any vegetable *débris*, we have some slight conception of the invaluable services which these little creatures render to agriculturists and fruit-growers.—*Farmer.*

THE BEST TIME TO PLANT TREES.

THERE is nothing, perhaps, on which most of us are more prone to dogmatize than on the subject of tree-planting. If we plant in spring and the tree dies, we are very likely to attribute the loss to the season, and decide never to plant in spring again. Or, if we plant in fall and have no success, then we are quite as decided against fall planting.

There is no doubt but that fall-planting has risks from which the spring is free. Trees which have not been transplanted, but have grown well in

the one place for twenty years, have been destroyed by the dry cold winds of winter. Not only evergreens, such as arborvitæ, balsam fir, hemlock spruce, and even Norway spruce, but deciduous trees, as cherries, tulip-trees, oaks, and many others with the best established reputation for hardiness. And then small things besides the risks of those frosty winds to dry up the little sap in them, are usually so much drawn out as to be seriously injured. The one great argument in favour of fall-planting is that where the trees escape all these risks it generally grows much stronger and more vigorous in spring than one planted at that time, as the bruised roots seem to heal, and the tree is ready to push out in the spring almost as well as many not transplanted. It saves a year.

But, after all, spring with most people will ever be the favoured time. The hot dry summer may come and destroy, just as the cold dry winds of winter may, and thus in some measure equalize the risk, but yet it is at this season that planting will be the most popular.

But there is one thing on which people need cautioning. A large number of persons start to plant as soon as the first bright sun shines through a snow-cloud, and before the earth is dry enough to powder about the roots. No matter how fine overhead, the earth should not be wet or frosty at the time of planting.

As a general thing the best time to plant trees in the spring season is just before the buds push, or even after they have started. This implies an active condition of the root, and generally occurs at a time when the earth is in the best condition for working in about the roots. As evergreens push later than deciduous trees, their removal may be extended long into May.—*Germantown Telegraph*, U. S. A.

AMBER.

THE complete history of amber is yet to be written, but when written it will form a most interesting and instructive volume. Known and valued from the very earliest times, it has a name in most languages, and its Greek name, *electron*, has left its impress upon our own and most other tongues. Nearly 2,000 years ago Pliny, the naturalist, wrote that amber was the fossil resin of an extinct cone bearing tree, and modern science can say of it but little more. In a short paper on this subject, laid before the last meeting of the American Association for the Advancement of Science, Erminnie A. Smith gives an epitome of what is known on the subject. The original amber-producing forest probably reached from Holland over the German coast, through Siberia and Kamschatka, even to North America. One of the most celebrated deposits is on the Peninsula of Samland, a portion of Prussia, nearly surrounded by the Baltic Sea. The northern part of this region, constituting the promontory of Brusterort, is hilly, and the coast banks are often from 150 feet to 300 feet high. At one time all the amber found here, even by the peasants in ploughing, belong to the German Government, the finder, however, receiving one-tenth of its value. For a peace in the Berlin Museum weighing 18lbs., the finder is said to have received a thousand dollars. During stormy weather, when the wind and waves beat violently against this coast, a great quantity of amber is washed up. The total yearly product is, however, apparently on the decrease, and so the price of amber is on the increase. Professor Zaddech, of Konigsburg, concludes that the trees yielding the amber resin must have grown upon the green sand beds of the cretaceous formation, which at the time formed the shores of estuaries where the lower division of the tertiary accumulated. Immediately over the amber producing strata rest the brown coal beds, the fossil plants found in which differ entirely from the amber bed flora. Many insects and plants are found embalmed in the amber. Over 800 species of the former have been named, and over 160 of the latter. When collected, it is, for the purposes of trade divided into classes, the best pieces being generally sent in the rough to Constantinople, where they are in great demand for the mouth-pieces of pipes. The smaller sized pieces are used for beads, &c., and the impure morsels for the manufacture of succinic acid or in the preparation of amber varnish. From other resins amber is distinguished by its hardness, its lesser brittleness, the much higher temperature required to reduce it, and its greater electric action. At a certain temperature it is also extremely flexible. The imitations of amber are numerous, but all are detected by the use of the electrometer. While the colour of true amber is generally yellow, it occurs in all shades, from pure white to black. Amber was intermingled with the myths and religion of the Greeks, their legends ascribing its origin to—

> . . . . the sweet tears shed
> By fair Heliades—Apollo's daughters,
> When their rash brother down the welkin sped,
> Lashing his father's sun team, and fell dead
> In Euxine waters.

Amber literature, indeed, has an interest of its own. Books in all languages refer to its many supposed qualities, and the insects contained in it have given rise to many a quaint metaphor.—*Times*.

LAC.

"LAC" (or as it is called in Hindustani, *lah*) is secreted by an insect (*Coccus lacca*) on the branches and twigs of certain jungle trees. The principal of these are the khusum (*Schleichera jujuga*) plas (*Butea frondosa*) and bier (*Zizyphus jujuba*). The lac from the first-mentioned, the khusum, is more highly esteemed than that from the others. To some extent the lac is found occurring, so to speak, spontaneously, and is collected by the forest tribes, and brought by them to the fairs and bazaars for sale. Where, however, there is a regular trade in stick lac, propagation of the insect is systematically carried on by those who wish for a certain and abundant crop. This propagation is effected by tying small twigs, on which are crowded the eggs or larvæ of the insect, to the branches of the above-named species of trees. The larvæ are technically called 'seed.' The larvæ, shortly after sowing, spread themselves over the branches, and, taking up positions, secrete round themselves a hard crust of lac which gradually spreads till it nearly completes the circle round the twig. At the proper season the twigs are broken off, and we must suppose them to have passed through several hands, or to have been purchased directly from the collectors by the agents of the manufacturer. On arrival at the factory, they are first placed between two powerful rollers, which by a simple arrangement, admit of any degree of approximation. The lac is then crushed off, and is separated from the woody portion by screening; it is next placed in large tubs half-full of water, and is washed by coolies, male or female, who, standing in the tubs, and holding a bar above with their hands, stamp and pivot about on their heels and toes until, after a succession of changes, the resulting liquor comes off clear. Of the disposal of the liquor drawn off at the successive washings, I shall speak presently. The lac having been dried is placed in long cylindrical bags of cotton cloth of medium texture, and which are about ten feet long and two inches in diameter. These bags when filled have somewhat the appearance of an enormous Bologna sausage. They are taken to an apartment where there are a number of open charcoal-furnaces. Before each of these there is one principal operator and two assistants. The former grasps one end of the long sausage in his left hand, and slowly revolves it in front of the fire; at the same time one of the assistants, seated as far off as the sausage is long, twists it in the opposite direction. The roasting before the glowing charcoal soon melts the lac in the portion of the bag nearest the operator's hand, and the twistings of the cloth causes it to exude and drop into a trough placed below. The troughs which I saw in use were simply leaves of the American aloe (*Agave americana*). When a sufficient quantity, in a molten condition, is ready in the trough, the operator takes it up in a wooden spoon, and places it on a wooden cylinder some eight or ten inches in diameter, the upper half of which is covered with sheet brass. The stand which supports this cylinder gives it a sloping direction away from the operator. The other assistant, generally a woman, now steps forward holding a strip of the agave of aloe between her hands, and, with a rapid and dexterous draw of this, the lac is spread at once into a sheet of uniform thickness which covers the upper portion of the cylinder. The operator now cuts off the upper edge with a pair of scissors, and the sheet is then lifted up by the assistant who waves it about for a moment or two in the air till it becomes quite crisp. It is then held up to the light, and any impurities, technically 'grit,' are simply punched out of the brittle sheet by the finger. The sheets are laid upon one another, and the tale, at the end of the day, is taken, and the chief operator paid accordingly—the assistants receiving fixed wages. The sheets are placed in packing-cases, and when subjected to pressure break into numbers of fragments. In this fresh state the finest quality is a very beautiful object, having a rich golden lustre. On seeing it thus, one cannot help feeling regret that it is not nice to eat—the best Everton toffee never looked more tempting. The above is the history of shell-lac, from its birth in the jungle to its appearance in the world as the commercial article. From the manufacturer it passes through the broker's hands to the merchant, and from him again to the manufacturers of varnishes, sealing wax, and other commodities of which it is an ingredient.

"The dark red liquor resulting from the washing above described, is strained, in order to remove all portions of woody fibre and other foreign materials. It is then passed into large vats, where it is allowed to settle; the sediment is subjected to various washings, and at last allowed to settle finally, the supernatant liquor being drawn off. The sediment, when it is of the proper consistency is placed in presses from which it is taken out in the form of hard dark purple cakes, with the manufacturer's trade-mark impressed upon them. This constitutes what is known as lac-dye. By the addition of mordants, this dark purple substance yields the most brilliant scarlet dyes, which are not inferior, I believe, to those produced by cochineal. The dye which is thus separated from the lac by washing is said to be the body of the insect, not a separate secretion."

One more extract we venture to make, which gives a description of the uses made of the flowers of the *Bassia latifolia* Roxb. Not only are the fruits of this tree used as an article of food, but "the fleshy deciduous corollas are likewise largely employed for the same purpose, and, in point of fact, constitute a staple and sometimes almost the only article of diet available to the poorer classes during several months of each year. Towards the end of February, or the beginning of March, as the crop of *mhowa* flowers approaches ripeness, the corollas, becoming fleshy and turgid with secreted juices, gradually loosen their adhesion to the calyx and fall to the ground in a snowy shower. The duty of collecting the fallen blossoms is chiefly performed by women and children; at dawn they may be seen leaving their villages with baskets and a supply of water for the day's use. Before the crop has begun to fall they take the precaution to burn away the grass and leaves at the foot of the trees, so that none of the blossoms may be hidden when they fall. The gleaners generally remain under trees all day, alternately sleeping and collecting the crop, and the male members of the family visit the trees once or twice during the day, in order to carry away what has been collected. At night, bears, deer, and other animals visit the trees to take their share of the crop. In the early mornings, and late in the evenings, the less frequented trees, on the borders

of the jungles, attract numbers of jungle and pea fowl. Cattle also are very fond of the flowers, and cow's milk has, in consequence, at this season, a strong flavour of mhowa.

"It often happens that the people who collect some from a considerable distance, in which case they erect with the branches of the sál a temporary encampment of huts, in which they live until the crop is all gathered in. In front of each of these huts a piece of ground is made quite smooth and hard, for the purpose of spreading out the flowers to dry in the sun. When perfectly dry they have a reddish-brown colour, and in size they have lost three-fourths of the original dimensions, and about half their original weight. It is the custom with some of the natives, before spreading them out to dry, to pull off the ring of minute foliaceous lobes which crowns the fleshy corolla. It is very difficult to obtain any trustworthy statements as to the yield of the mhowa trees. A first-class tree, I have been told, will continue to shed its blossoms for fifteen days at the rate of 120 pounds a day, but this estimate is, I believe, at least double what it ought to be. The rent of the trees varies with the abundance of them in the district, the quality of the previous rice harvest, and various other circumstances affecting the demand and supply. Two-pence to four shillings were the extremes of prices which in various places, had, I ascertained, been actually paid for permission to collect. As does the rent of the trees, so the saved crop varies much in price —the limits being from 120 to 480 pounds for the rupee, or two shillings, but when as is most frequently the case, the exchange is in kind, the merchants only give a small quantity of salt, and six or eight pounds of rice for a maund (80lbs) of mhowa. During the famine in Manbhoom the price of mhowa averaged about 24lbs. for the rupee.

"Two maunds of mhowa are stated by some to furnish a month's food to a family consisting of a father, mother, and three children. It is however, seldom eaten alone, being mixed with the seeds of the sál, or with the leaves of jungle plants; sometimes a small quantity of rice is added. It is the custom to cook but once a day and each member of the family helps himself whenever he feels hungry.

"When fresh the mhowa has a sweet taste, with an odour somewhat suggestive of mice; when dried, it presents some resemblance to the inferior kinds of figs. Cooking renders it vapid and utterly devoid of flavour. On distillation, the newly dried flowers yield a highly intoxicating spirit called *daruu*; this is generally diluted with from five to ten times its bulk of water, and is then sold at about the rate of a penny for a quart. Its ordour is most offensive to Europeans, but British soldiers have been known to secure for themselves the pleasures of intoxication by drinking it with held noses, as a child takes a nauseous draught. By careful distillation it is possible to get rid of the essential oil which causes the unpleasant flavour. From the seeds a sort of oil is expressed, which is used for cooking purposes and to adulterate ghee. Although the natives protect such mhowa trees as exist, I am not aware that they do anything to increase the number.—*Nature.*

PHOSPHATES AS MANURE.

A CORRESPONDENT of the *Madras Mail* writes from Scotland:—
"The Highland and Agricultural Society have issued their usual annual volume, and it is more varied and readable than it generally is. Amongst other articles it contains an account of experiments of growing crops, with various manures, and particularly of trials between dissolved and undissolved phosphates. Phosphates are now generally derived from ridges of phosphatic rocks, and they are ground down into powder, and our custom hitherto has been to dissolve them, and convert the phosphate into superphospate by the addition of sulphuric acid—which dissolves the powdered rock. These phosphatic reefs of rock are found in various parts of the world, and they exist with you, and if the ground phosphates are found to have as good an effect on the growth of plants in Southern India as they have with us, they will ultimately prove of more value to the country than the gold-yielding quartz. With the machinery now in use, the expense of crushing the phosphatic rocks is not an expensive operation. Sulphuric acid is not dear with us; but still its use almost doubles the cost of the manure, and with you it would probably do a good deal more. For the growth of cereal crops nitrogenous manures are more profitable than those of mineral origin, because the return is greater and more immediate, still it is proved by experience that Liebig's theory of keeping up the fertility of the soil by returning to it the minerals extracted by the crops, has a basis of truth, and that they do add to the produce of the soil, and that more permanently than nitrogenous manures, which we apply in the form of sulphate of ammonia, nitrate of soda, and guano. Phosphates seem better adapted to the growth of green crops than of the cereals, and it is evident that they are very favourable to the growth of leguminous plants. Wherever they are applied to old pasture land, there is an immediate increase and luxuriant growth of all the natural legumens, such as wild peas and vetches, while, with a continued use of nitrogenous manures, these totally disappear from the pastures. Dr. Voelcker, one of our most eminent of agricultural chemists, a short time ago wrote that insoluble mineral phosphates, such as ground phosphatic rock whether contained in 'coprolites, apatite, or rock guano scarcely produce a visible effect on vegetation, even when they are applied to the land in a finely powdered condition, and in large quantities.' This statement was accepted as truth till the Aberdeenshire Farmers' Club determined to test it practically, and experiments have shown that the application of the undissolved ground rock gave 40 per cent. more barley, and 70 per cent. more turnips than when nothing was applied. The great point is fineness of division of the article used, and, if ground to an impalpable powder, there is no doubt but that the fertility of the land can be much improved by the use of undissolved phosphatic rock. Every soil has its own deficiencies, either natural, or from the previous course of cropping, and discrimination and observation are required to use manures to the most profit. Sir Joshua Reynolds replied to some one asking how he mixed his paints, that he did so 'with brains, sir,' and the farmer all the world over must mix his manures with the same not over plentiful, but very valuable ingredient if he wishes to derive the most profit from them."

THE CEDAR OF LEBANON.

IN the lately-published part of the journal of the Linnean Society, Sir J. D. Hooker publishes an account of the discovery of a variety of the cedar of Lebanon by Sir Samuel Baker on the mountains of Cyprus. It is interesting to note that, though the botany of his island has often been examined, this is the first record of such a discovery. The trees were described by the monks of Troodítissa Monastery as existing only on the mountains between the monastery of Kyker and the town of Khrysokus. This is a pathless and almost inaccessible region. The monks considered the wood to be the Scriptural "Shittim wood." Sir Joseph Hooker describes the specimens forwarded to him through the kind offices of the Marquis of Salisbury as differing from the known forms of *cedrus* in the shortness of their leaves and the smallness of the female cones. He thinks that the now far separated cedars of the Himalayas, Lebanon, the Taurus, and Algeria were races of formerly more generally distributed trees, and that their isolation was due to geographical and climatic changes in the area over which the species was distributed. Their isolation is now very great. The nearest point to the Lebanon at which cedars have been, up to this, found, is the Bulgar-dagh chain of the Taurus in Asia Minor, and from that point, forests of *C. Argentea* extend eastward to Pisidia and northwards to the Anti-Taurus. At a distance of some 1,400 miles from the cedar forests of Asia Minor, and separated from them by the whole breadth of the Mediterranean Sea, are those of Algeria, containing the Atlas cedar (*C. Atlantica*). Proceeding eastward from the Lebanon, we come after another 1,400 miles to the cedar forests of Afghanistan, which extend thence continuously eastward along the Himalayas almost to the confines of Nepaul. This cedar (*C. Deodara*) is perhaps the most distinct in habit of the three forms. As to the Cyprus cedar, Sir Joseph Hooker says that in size of cone, and size, form, and colour of leaf, it approaches the Algerian far more closely than it does any Taurian, Himalayan, or Lebanon cedar.—*The Times.*

THE USES OF THE POTATO.

IN France the farina is largely used for culinary purposes. The famous gravies, sauces, and soups of France are largely indebted for their excellence to that source, and the bread and pastry equally so, while a deal of the so-called cognac imparted into England from France is distilled from the potato. Throughout Germany the same uses are common. In Poland the manufacture of spirits from the potato is a most extensive trade. "Stettin brandy," well-known in commerce, is largely imported into England, and is sent from thence to many of our foreign possessions as the produce of the grape, and is placed on many a table of England as the same; while the fair ladies of America perfume themselves with the spirit of potato under the designation of *Eau de Cologne*. But there are other uses which this esculent is turned to, abroad. After extracting the farina, the pulp is manufactured into ornamental articles, such as picture frames, snuff-boxes, and several descriptions of toys, and the water that runs from it in the process of manufacture is a most valuable scourer.

For perfectly cleansing woollens, and such like articles, it is the housewife's panacea; and if the washerwoman happens to have chilblains she becomes cured by the operation.—*Sydney Mail.*

DISCOVERY OF KEROSINE IN NEW SOUTH WALES.

THE *Sydney Morning Herald* of 25th March says:—"For some ten months boring for coal has been going on at Moore Park, near Sydney. One day last week the rods were lowered, and when they were within eight inches of the bottom were set in motion, whereupon a quantity of oily matter came up outside the stand-pipe, and continued to flow for ten minutes. At first its appearance was dark brown, and on falling it became immediately covered with a thick foam or froth; afterwards it became milky white, and finally changed to water with an oily scum on it. Mr. Coghlan bottled some of the liquid, which showed oil on the top very freely, and ever since the gush of brown liquid there has been an oily scum on the water discharged from the bore. On Friday, just as boring was commenced, there was a gush of oily matter similar to the first, only that the force of this discharge was greater, and the flow lasted for half-an-hour before it was replaced by water. Mr. Coghlan is strongly of opinion that the liquid is crude kerosine, since it has the smell of that substance. During the day the spot was visited by Mr. Wilkinson—the Government Geologist; Mr. Pitt, Mr. Peate, Mr. Street, and several other gentlemen, whose interest had been stimulated by the supposition that Mr. Coghlan had struck

oil. The mysterious liquid was the subject of much attention from these gentlemen, one of whom confirmed Mr. Coghlan's opinion that it was crude kerosine. Others of the party would not venture to express a decided opinion as to its nature, although it was being washed out before them and had increased in volume very considerably during their stay. Mr. Wilkinson took a bottle full of the liquid away with him for analysis, but this analysis is not yet completed. There is no doubt, however, that its results will be watched with intense interest, because the discovery of a payable oil well in the vicinity of Moore Park would be of immense importance and value, not only to Sydney, but to the colony generally."

MADRAS AT THE MELBOURNE EXHIBITION.

DR. BIDIE has drawn up a very interesting catalogue of the specimens sent for display to the Melbourne Exhibition. The articles selected will give one a good idea of the products of this presidency, and it is hoped that by means of the Melbourne and Sydney exhibitions a trade will gradually spring up between the two countries. The Madras Presidency is capable of supplying the wants of Melbourne in respect to such articles as tea, coffee, tobacco, oil seeds, vegetable, fish oils, &c. The specimens of sugar and spices should attract attention there, but the produce of the Straits Settlements, Java, and the newly acquired Fiji islands will, we think, more than supply the demand. The Madras Government, the Nizam of Hyderabad, certain native merchants and the owners of the coffee and tea estates in the Wynaad, Nilgiris, and the Shevaroys have sent specimens, and in making the selections and cataloguing them, Dr. Bidie is likely to secure greater attention for the Madras exhibits at Melbourne than was paid them in Sydney at the recent exhibition. The specimens of mats and carpets came chiefly from Hyderabad; the specimens of metal work in brass and copper were from Tanjore and North Arcot. Some of the brassware were the product of the industry of Malabar, but we believe that the palm will always be borne by the Tanjore workmen whose designs are not only good, but the system they adopt of inlaying the one metal with the other such as brass with silver and copper with silver displays great mechanical and artistic skill. The Sandal and Ivory ware are exhibited by G. Chinna Veeranna, the manufacturer, whose exhibits at the last Fine Arts Exhibition here attracted much attention; fancy basket work made in Pulicat, and the rattan baskets from the Friend-in-Need Society are included in the Madras exhibits. The cotton fabrics are from the Cannanore Central Jail; the embroidery is exclusively a Madras manufacture, and it is to be regretted that there is every probability of the "art shortly dying out" owing to the little demand for articles. Embroidery is an industry introduced by the Mahomedans. Under the head "native costumes" we note that supplies of Madras palempores, handkerchiefs, and women's cloths are included. Fish oil which is largely available in Malabar is exported from the west coast, but the price seems to be rather high. There is a pretty large assortment of fibres for which this presidency is noted. "Fibrous plants abound in almost every hedgerow," says Dr Bidie, but "the great obstacle in the utilisation of this mine of mineral wealth has been the want of some simple and efficient machine for extracting the fibre, which would do its work without impairing the quality of the produce." Vegetable oils are, the groundnut, gingelly, castor, lamp, and cocoanut; the three first named are exported to France; the two last named are chiefly retained for local consumption. The tobacco specimens are chiefly those obtained from the Madura and Trichinopoly districts and from the Lunkahs in the Godavery delta. The trade in these staples is steadily on the increase, the shipments of cigars to the Straits Settlements, Mauritius, and other places, were never so large as they are now, and we have reason to believe that in Australia, good Trichinopoly and Dindigul cheroots will find a ready market. The specimens of dyes and drugs, indigo and cinchona, will take prominent position. The produce of the Government Cinchona estates on the Nilgiris, to say nothing of the large supplies grown and manufactured by private enterprise, will form a conspicuous feature in the Madras contributions. Specimens of Jalap and Senna have been included. Tanned and Dyed skins, pulses grain, and spices, are also among the exhibits; Madras tanned skins have been successfully introduced in Boston and in the United States of America, and we see no reason why they should not find a market in Australia. Madras exhibitors have been invariably commended for their exhibits of condiments, chutnies, and jellies, at exhibitions held in Europe and America, and we think there will be a market for these in the Australian colonies. The many samples of tea and coffee will, it is hoped, be appreciated by colonial merchants. It may be of interest to note that, according to the catalogue, there are in this presidency seventy-nine tea estates, with an area of 9,002 acres, and that tea cultivation is on the increase. The annual yield of the Nilghiri tea estates is 253 lb. per acre, the local average price of Nilghiri tea is Re. 1-4 to 1-8 per lb. The exports of tea to foreign ports from this presidency in 1878-79 were 204,630 lb., valued at a little more than two lakhs of rupees.—*Madras Standard.*

THE ROYAL BERKSHIRE SEED ESTABLISHMENT.

THE following is an account of the Royal Berkshire seed Establishment at Reading, near London, and is extracted from a Metropolitan Agricultural Journal:—

The Proprietors of this vast concern, which had now attained world-wide reputation,—Messrs. Sutton & Sons,—have long been among the foremost seed firms of the country, and can look back, as do almost all who have been commercially prosperous, upon a rapid growth from comparatively small beginnings. There are, however, a succession of generations in the business. The grandfather, with whom it began—growing out of the occupation of a corn-dealer and miller, half a century ago—has sons and grand sons now in the firm, and since the days of his earlier catalogues, which were shown me, it has grown up from very humble dimensions. Messrs. Sutton & Sons lay themselves avowedly open to cultivate a foreign and colonial trade. Nothing we can imagine is so trying to the temper of the agriculturist—or, for the matter of that, the amateur also—as to find, after he has taken great trouble and every reasonable precaution in sowing the seeds from the growth of which he anticipated profit, that they will not come up. In the frame of mind to which his disappointment gives rise, the enraged agriculturist is not disposed to discriminate with any degree of nicety between the parties he may be disposed to hold responsible for his disappointment. Sometimes, no doubt, as indeed recent trials have proved, he is the victim of an unscrupulous tradesman, and finds that he has had foisted upon him seeds which were never meant to grow; but more frequently the mischief may have been done unwittingly, and where the seeds have undergone transit, it is more frequently due to injudicious packing than to any other cause. Unsatisfactory results are sometimes experienced even when the seeds are packed by a competent man, to order. It is evident that safety cannot be insured unless the seeds are packed by the grower, at the right time, in such convenient parcels that they need not be opened until the ground shall be ready for the reception of the seeds. For the benefit of our distant readers we may mention that Messrs. Sutton & Sons have directed particular attention to this branch of their trade, and after a series of exhaustive experiments they have succeeded in hitting upon a system of packing, whereby grass seeds, farm seeds, vegetable seeds, and flower seeds may be transported, without deterioration, to any distance, to the varied climates from which their export orders come.

We were shown a room where some export orders where in course of being got ready, and we noticed that the packets for every order were placed in ingeniously constructed tin cases—of which we observed a large quantity in stock, specially manufactured for them—into which it is impossible for any damp to penetrate. These, of course, are for such seeds as are sent out in somewhat limited quantities; clover and grass seeds, which are exported in considerably greater bulk are packed as carefully in huge zinc-lined cases or casks, which the exigencies of trade allow of being rendered serviceable in the return journey for the carriage of tallow, &c. From the export department we were taken to the farm seed order room, which we believe is the largest of its character in the world, being no less than 180 ft. long by 60 ft. wide, one great peculiarity being that there are no pillars to obstruct operations, the roof being light and self-supporting. Numerous were the cleaning rooms through which we were taken, and most careful, it was evident, are the firm to keep up their prestige for supplying none but the best seeds. We were at first surprised at the quantity of apparently useful, if not first-class, seed which was thrown on one side by the employés but we could at once understand that it is this strict exclusion of inferior or damaged seed that has earned for the firm the reputation they enjoy.

The magnificent fabric upon which the reputation of the vast Reading enterprise is built, lies at the very foundation of the purity of stocks and freedom from adulteration. If the seeds are pure and the stocks have been kept true by constant selection from year to year for many years, they will produce plants of a fixed and constant type, which may be trusted to satisfy customers and do credit to the firm. Every year stock seed is provided for, in case it should be wanted; the best specimens are gathered from the fields and selected. If the character hinges upon leaf, or flesh, or shape, or all combined, a careful examination is made, so as to be absolutely true of its kind. At the proper time the selected specimens are planted out, far apart between the plots. But as, whenever a sufficient stock of first-rate merit has been obtained, it is used as long as it is alive, it thus comes to pass that only two or three kinds are every year required for the replenishment of the existing stocks. That mangel seed is perhaps five years old; it was the produce of a remarkably good year, and can be trusted more confidently than even that which was harvested last year to produce trustworthy plants. It is in this way that the seed bags of stock seed which I saw in one division of Messrs. Suttons' warehouses are from time to time replenished, and the apartment set apart for their security is kept fallen apartment which may be compared to the "deed room" of a mansion. It should be a safe, for the loss of it would be a very serious loss indeed.

Starting with the stock seed and seed fields in Essex, Kent, Cambridgeshire, Suffolk, Beds, Herts, Huntingdon, and Worcestershire, where the plants obtained from it are set out, we come at length to the second harvest time, when the seed from all these plants is threshed and cleaned, and despatched to Reading—every bag with its ticket inside as well as outside, to ensure its identity being known. These bags receive each a home label, indicating kind and date and grower, and they are warehoused until cleaned and ready for sale, when they are stacked each in its proper place until wanted for use.

On the several great warehouse floors—200 feet by 60 feet in area—we saw immense stores of Italian rye-grass, perennial rye-grass, various other grasses, clovers, &c. Italian rye-grass is principally produced in the fens of Cambridgeshire and Huntingdon, and the other rye-grasses, are grown chiefly in Scotland.

The varieties of farm seeds which are in most frequent requirement have, special stores devoted to them; thus, mangold, swede, turnip, &c., seeds have separate and capacious stores. Messrs. Sutton & Sons for many years have enjoyed a very high reputation for the quality of their grasses, and for these again they have two separate stores. The stock on hand is enormous; but large as was the supply at our visit, we were told that ere long it would all be gone. Each stock of natural grass is gathered by hand by women in Germany, especially for Messrs. Sutton, and is kept entirely distinct. A good deal of the higher class of seed is also hand-picked again on arrival in England—a tedious process but strictly carried out—and these varieties are afterwards mixed to suit the nature of the soils required to be sown. When we mention that there are some twenty-

three different kinds of natural grasses and clovers more or less fitted for permanent pastures, it may be imagined that considerable care has to be exercised in this department. Sufficient seed was sent out last year by this firm to cover no fewer than 28,000 acres with various kinds of grass.

The vegetable seed store is worthy of particular remark. It is a very hive of industry, and here it is that one comes first perhaps upon the admirable "system" which prevents the almost innumerable mistakes which would otherwise occur in an establishment of such extent. This room measures, we understand, 159 feet in length, by 30 feet in width, and 20 feet in height, and is fitted round with innumerable drawers, each "after its kind" distinctly labelled. The centre of this room is occupied by rows of small tables or counters upon which the attendants range the packets for each separate order, as they shall have fetched them from their proper drawer. An attendant of a somewhat higher standing next takes the order, and, comparing it with the packages which have been gathered together, sees that all is correct. We may here mention, perhaps, that throughout the whole of this extensive establishment everything that modern ingenuity can devise to facilitate and lessen labour has been done by Messrs. Sutton & Sons. The sub-division of work has been carried to a great pitch of perfection. The system devised for despatching goods not only greatly quickens the execution of orders, but greatly lessens the possibilities of mistakes. The flower seed store and the bulb-room are very much similar in their arrangements to the vegetable seed store, the most puzzling matter about them being the infinite number of varieties which are daily under manipulation. From the stores one passes to the packing-room, where the orders are put together, into secure packages for transit, and when it is considered that the orders sometimes amount to six or seven hundred in a day, it may be imagined what care is requisite that "system" shall everywhere be observed.

How large as well as various is the business of the firm, appears from some of the figures which were shown me—for Messrs. Sutton were good enough to let me see their books. The sales of grass seeds, mangel wurzel, swedes, and turnips, were last year enough for nearly 200,000 acres of land devoted to these kinds of crop alone. The business in grass seeds has increased a hundredfold during the last quarter of a century—that of flower and garden seeds, though originally proportionally larger than the other, has increased about as much.

So much then, briefly, of the business which brings grist to the employers' mill. But now, one word or two anent the interest employers manifest towards employed. Besides arrangements by means of which those who choose can remain in comfort during the intervals devoted to refreshment, there is a spacious library and reading-room provided, well supplied with books and periodicals, and which is open whenever business is not going on.

We cannot conclude our little sketch without a word or two about the handsome and instructive catalogues and guides which are annually published by this firm. As long ago as 1840 when nothing but bare unpriced broadsheets, specifying the kinds of seed in stock, were the order of the day, Mr. Sutton first issued a modest little compilation, which, originally only professing to offer a few hints as to how an amateur might keep his garden stocked without further assistance throughout the year, has gradually developed into an elaborate Annual, elegantly illustrated with charming chromo-lithographs, whilst the engravings, 500 in number, are all drawn from growing specimens. The articles are written especially for this work. Amongst the subjects treated upon in this year's edition, we notice "A Year's Work in the Kitchen Garden, January to December." "The Rotation of Crops in the Kitchen Garden." "The Cultivation of Vegetables," "The Cultivation of Flowers," "The Cultivation of Bulbous Flower Roots." "The Cultivation of the Potato," "The Eradication of Garden Pests" "The Laying Down and Improvement of Garden Lawns, Croquet Grounds," &c. Included in this Guide is a complete descriptive list of all the best varieties of vegetable seeds, flower seeds, and potatoes, so that every reader can have no difficulty in selecting the seeds best suited to his requirements.

In addition to this, the firm issue, for the information of those interested in the subject, a reprint of Mr. Sutton's "Permanent Pastures," alluded to above, and an extremely useful "Tropical Garden Guide," with notes on cultivation, which should prove very valuable to all interested in gardening, whether resident in Europe, Asia, Africa, or America. With a business energy and enterprise unequalled perhaps in the history of the seed trade, Messrs. Sutton have agents for the sale of their boxes of seeds in every part of the world, excepting the United Kingdom; and those abroad who would ensure success and prevent that vexatious disappointment which often happens, should not fail to find out by the papers where Sutton's Reading Seeds can be obtained.

AGRI-HORTICULTURAL SOCIETY.

WE take the following paragraphs from the report of the Committee of the Agri-Horticultural Society of Madras, for the year 1879:—

During the past year the Committee of this Society has, as usual, steadily persevered in its efforts to benefit and advance the Agriculture and Horticulture of the country, and has, with that object, made sundry experiments, with varied success. The year was very favourable to vegetation, the rainfall being well distributed and above the average, being from the published returns of the Government Observatory, 51·25 inches, as against an average of 48·94 inches. Fresh vegetation was slightly checked by unexpected hot landwinds, which blew so late even as 20th September, and ferns and roses suffered considerably in consequence, but happily no permanent damage was done.

Grasses, Fodder-plants, &c.—Further consignments of grass seeds have, from time to time, been received from Queensland, Australia, and distributed to correspondents in different parts of the country, and tried in the gardens, without any more satisfactory results than those detailed in the last Annual Report. The observations then made on the subject still hold good, none of these grasses appearing to be able to stand our long, continued dry weather, without constant watering and attention, which renders their useful cultivation impracticable. No further results have been obtained from the famous paper-making grasses *Esparto* and *Ligium spartium*, the few plants which germinated having dried out. Experiments with *Prickly comfrey* have failed, the plants which were in the gardens, though receiving rather more than their fair share of attention, having one by one perished. The gigantic fodder grass, *Euchlæna (Reana) luxurians*, may be stated to be a success. Several patches of ground in the experimental gardens have been sown and planted with it, and have produced most luxuriant crops, both when the plants were allowed to remain in the seed beds, and when transplanted. Self-sown plants also have grown well. It seeds freely and abundantly, but if allowed to seed, dies down. If cut while young, it reproduces itself repeatedly, even in the hot weather, but requires abundant water and manure. All animals seem to devour it voraciously, leaf and stalks, and it is difficult to save the seed from birds and squirrels. The Committee strongly recommend its cultivation. Efforts to distribute the "Rain Tree" (*Pithecolobium saman*), have not been relaxed, and many young trees, and some small parcels of seeds have been sent to different parts of Southern India, but unfortunately the seed was scarce, being produced only in very small quantity. There will probably be a more abundant crop this season, when requisitions which have been received from many distant parts, including South Africa, will if possible be complied with. Seed of *Cytisus prolifera* was received in August from Kew with a high character of the plant as forage. The seed was as usual sown in the garden and distributed to correspondents for experiment, but no satisfactory result can yet be reported almost every seed which germinated having speedily perished.

Liberian Coffee.—The introduction of Liberian Coffee into Madras and its neighbourhood may, the committee think, be declared a failure. The plants in the gardens have most of them perished in spite of every care, and those that survive still maintain the character of shrubs rather than of trees, though now upwards of three years from the seed, having been received in the gardens from Kew in July 1877. The healthiest plants the Society now possesses are from cuttings made from what the planters call expressively "Gormandising suckers." The plants in the ground amongst the shrubs in the ornamental garden, are still in better health than the survivors of those that were planted in the open in the experimental garden; but they grow very slowly, and though they have two or three times flowered, any fruit which has set hitherto has burned black and fallen

Cinchona.—Frequent and heavy demands continue to be made on the Society for cinchona seed, from various places, particularly Ceylon and the Wynaad, which are to as great an extent as possible complied with. *C. officinalis*, *C. succirubra*, and *C. Calisaya* are the sorts most frequently asked for. Requisitions for *C. Ledgeriana* continue to come in, and, to the Society's regret, remain unsatisfied.

Mahogany.—A considerable quantity of Mahogany seed has been received during the year from Dr. King, Calcutta, and Mr. Woodrow, Poona, and about two hundred young trees were raised. Many of these have been presented to the Robinson Park, the Gunpowder Factory, and other public institutions in Madras. A few have been sold, and others have been distributed to subscribers.

Grevillea robusta.— A large batch of young trees has been raised from seed procured from Mr. Cameron, Bangalore, and Dr Thwaites, Ceylon. The tree is exceedingly graceful, but does not flower in Madras; and the timber, though very beautifully marked, is, at least as grown in Madras, too light to be of great value.

Landolphia.—One of the most important plants recently introduced is *Landolphia sp.*, the source of the India-rubber obtained from East Africa. After several attempts, twenty-four plants reached Madras in good order in a Wardian case, sent by Dr. Kirk, H. B. M.'s Consul-General, Zanzibar, in May last. One plant was given to Mr. Cameron of the Lal Bagh, Bangalore, and the others, though growing very slowly, appear to be in excellent health, in the gardens.

Gardens.—No serious alteration has been made in the gardens during the past year. They continue to be maintained in very excellent order, and look well, as they have done throughout the last two seasons, which have been very favourable. The Committee hopes, very shortly, considerably to extend the area of the gardens by the purchase of parts of the cocoa, nut topes, to the south and west of the ornamental gardens, room being very much wanted for the many new and rare trees and other plants introduced within the last two or three years.

AGRI-HORTICULTURAL SOCIETY OF INDIA.

THE usual Monthly General Meeting was held on Thursday, the 25th June, 1880. W. H. Cogswell, Esq., V. P., *in the Chair*.

The following gentlemen were elected Members:—Baboos Jodoolaul Mullick, Bejoy Kissen Mookerjee, Kissorelal Gossain, Mohesh Chunder Chowdry, Bholanath Dhur, Messrs. Henry M. Lennox, and William Oldham, S.C.

The names of the following were submitted for Membership:—Mr. J. G. Macdonald, Calcutta,—proposed by the Secretary, seconded by Mr. G. L. Kemp.

Mr. A. Sprenger, Executive Engineer, Upper Assam Division,—proposed by Mr. F. St. C. Grimwood, seconded by the Secretary. Rajah Rajendro Narayan Roy, Joydebpore, *viâ* Dacca,—proposed by the Secretary, seconded by Baboo P. C. Mittra, Mr. W. F. Swan, Calcutta,—proposed by the Secretary, seconded by Rajah S. A. Ghosal. Mr. James Murray, Calcutta,—proposed by Mr. J. Martin, seconded by the Secretary. *Rejoined.*—Mr. D. G. Landale, Calcutta.

Contributions.—Seeds of *Cytisus proliferus* and *Hymenæa Courbaril*, From the Royal Gardens, Kew. The former yielding a good fodder; the latter is a fine timber tree, a native of South America, where it grows to an enormous size. A valuable resin, resembling the Anime of Africa, exudes from the trunk. These seeds are available to Members.

A few roots of Tydæas and some Begonias. From Dr. T. Beaumont.

Seeds and plants from the Nicobars. From E. H. Man, Esq. Letters were read—.

From Under-Secretary, Government of Bengal, inquiring if the Society can find room to provide for the necessary accommodation for models and drawings of agricultural appliances, &c, for the inspection of the public and persons interested. *Resolved*—that all available space be granted for this purpose.

From the Secretary, Bijnour Agricultural Institute, announcing the formation of the Institute and applying for assistance in the shape of plants, seeds, and publications.

Resolved—that this be granted to the best of the Society's ability.

From Lieut.-Col. M. Millett, Mussoorie, in reference to the allusion in Gardener's report at last meeting to *Clianthus Dampieri*. Col. Millett states that he succeeded very well a few years ago, when all Mooltan, in raising this plant "a very hot and dry climate, rain fell then 5·64, very cold winter, grown in pots, one seed in each pot, soil one part, best leaf mould, three parts well washed blue river-sand, a few lumps of charcoal for ventilation, water as required, but not excessive, flowers fine and perfect, much admired, seeded freely."

From Col. W. M. Lees, offering to obtain plants and seeds for the Society from his brother, the Governor of Lubaon. Accepted with best thanks.

From H. A. Firth, Esq., to the same effect in respect to Demerara. Also accepted with best thanks.

MINERALOGY.

RULES for the working of the coal deposits on the southern face of the Khasi and Jaintia Hills are under the consideration of the Government, "and the Chief Commissioner is ready to give every encouragement to the development of these resources," which, though difficult of access, may yet be made available for the purposes of tea manufacture.

IMPORTANT GOLD DISCOVERIES IN VICTORIA.

EARLY last month, according to the Melbourne *Argus*, a discovery was made in the Talbot district, Victoria, which promises to be of the greatest importance, with regard to the future of mining in that locality. The discovery was the finding of splendid gold on the bottom of the shaft of the Rip Van Winkle Company. The shaft is situate very near the centre of a stretch of the deep ground, about two miles in length, and the company is the first to have touched it, between the Sadowa Company's claim which yielded nearly a quarter of a million sterling in gold, and that of the Union Extended Company, higher up the lead. In two or three places during the past few years tunnelling has been carried on to some extent to catch the deep ground, but it has not been found till now. It appears certain, however, that several claims must all benefit by the recent discovery being right on the line of the deep ground. This discovery in the Rip claim is expected to open up about four miles in all of one of the richest alluvial leads in the colony. A tin dish full of the washdirt taken off the bottom of the shaft yielded a pennyweight of coarse gold. "Mining affairs on Ballarat have been very brisk for some months past, owing to the opening up of the Sebastopool lines of reef, and they have been further improved during the past few weeks by the discovery of what is supposed to be an extensive and rich run of wash dirt in the claim of the East Hurdsfield Company on Ballarat. The singular richness of this washdirt is still a source of surprise, and leads up to much speculation, because as no one ever expected that such a grand discovery would be made; so no one now knows where it is likely to terminate, and, although the general impression is that the washdirt is what is generally known as a reefwash, *i.e.*, a wash deposited on a flat or slightly shelving surface, much higher than the gutter—it is not definitely settled whether it is so or a missed main lead or gutter. If it turn out to be, as anticipated, a reefwash, there is no knowing to what extent it may be traced yet, as no evidence of its existence seems ever to have been revealed to the early diggers, whose sole object was to follow the deep gutters, which were supposed to contain the richest of the washdirt. The elevation at which it is found is very much in favour of the reefwash theory, and, that being the case, many people are of opinion that the Hurdsfield group of claims is not the only locality in which it will be found, but that it may be traced along the terraces of the Golden Point and Gravel Pits leads, right into, and possibly beyond, the centre of the City of Ballarat. That the progress of mining in the Ballarat district is substantial, is well shown by the returns for the last, and previous weeks. These show that the yields for the week before last exclusive of the Clunes mines and of co-operative parties, amounted to 3,599ozs. 4dwt. 12gr., and the dividends £5,050, while for last week the yields—also exclusive of Clunes and co-operative parties—amounted to 4,620ozs., and the dividends—with the same exclusion—to a trifle over £6,000.

SAPPHIRES IN SIAM.

THE following interesting memorandum is by Mr. W. H. Newman, Acting Consul-General at Bangkok :—

The year 1879 will long be memorable in the provinces of Battambong and Chantaboon for the discovery of valuable sapphire mines and for the great influx of foreigners, chiefly from British and Independent Burmah, to work the same. There have long been mines of inferior value in this neighbourhood, and about five years ago new mines were discovered by a native hunter. Being, however, in a very remote and secluded position, it was some time before the fame of the new mines spread to the Burman and Indian gem traders and miners. Some individual diggers, however, having found their way to the mines, and having returned to Rangoon and Calcutta with the proceeds of their work, realised very large sums, and a rush for the new mines commenced and continued throughout the last year, during which many thousands of British subjects passed through Bangkok from British Burmah on their way to the mines. The arrival of these large bands of armed strangers caused considerable alarm among the natives of Chantaboon and Battambong, who could scarcely be persuaded that the country was not invaded once more by the old hereditary enemies of Siam, the Burmans and Peguans. The miners, however, by their peaceable behaviour restored confidence, and the country people soon were glad to sell them all kinds of provisions at enhanced rates. The miners, in their haste to become rich, disregarded all considerations of health, and immense numbers died from jungle fever. The Governor of the province has hitherto levied 2¼ ticals (5*s.* 7½*d.*) from every man working at the mines, and this is cheerfully paid. Good order has hitherto been maintained, and the Governor has appointed a British subject named Kum Sai to act as headman and to collect the license duty. The Siamese authorities do not regard with entire complacency this conveyance from their soil of these valuable gems without the payment of any royalty. No definite proposition has, however, yet been made to impose any other than the license-tax above-mentioned. There would probably be found considerable difficulty in collecting any sort of *ad valorem* duty. As it is, the discovery of the most valuable stones is kept as secret as possible by the fortunate finders, and should any *ad valorem* duty be attempted to be imposed, the tax-gatherer would probably be defeated by craft or force. When Admiral Coote was here, I was anxious to show him some good specimens of these sapphires, and called for some of the miners who were in Bangkok on their return from the diggings. One of them, a poorly clad and miserable looking individual, produced a few small stones, and, after a great deal of coaxing, was induced with many precautions to give us a private view of his great prize, which was a very large sapphire in the rough, which he valued at Rs. 20,000. He would probably not have shown this stone at all had he not been on the point of leaving, in a steamer. Owing to the secrecy thus observed by the possessors of valuable gems, it is impossible to give any estimate of the total value of stones found, but that individuals have made very large profits is certain. There is a man now in Bangkok who dug out a stone which he offered for sale in Chantaboon at Rs. 1,000, but did not find a purchaser. He went with it to Rangoon, where he was offered Rs. 15,000 but, having then awoken to the value of the stone, he declined to sell, and took it to Calcutta, where he eventually obtained Rs. 30,000 (£3,000) for it. Now, however, there are many experienced gem merchants established in the neighbourhood of the mines, and something like the real value of the stones can be obtained by the miners on the spot. Many of the miners finding themselves in cash have invested in the luxury of wives taken from the Siamese population, and the value of marriageable young women, who are at all good looking, has in consequence gone up to a very high figure. The largest sapphire hitherto found, which I know of, weighed 370 carats in the rough, and when cut turned out 111 carats of the finest water. The ruby, onyx, and jade are also found in the district, but the quality of none of these is such as to make them very valuable.

FORESTRY.

THE Mysore Government is not behind-hand in its efforts in the direction of forest protection and extension. The Forest Department has of course been under the charge of sundry European officers of the department, and in view of the approaching restoration of the province to native rule, the progress report of Forest administration for 1878-79 is more than ordinarily complete in the matter of details. Extensive reductions have recently been effected in the *personnel* of the department, it being intended under native rule to throw the bulk of the work on the shoulders of the district revenue officers. The purely state forests extend to 454 square miles, which will be largely increased when certain surveys now in progress are completed. The subject of proper demarcation has been fully discussed in recent years, and for a time the plan of planting a thick belt of the quick-growing casuarina trees as a protecting boundary has been favorably entertained, but it having been ascertained that the casuarina readily takes fire and passes it on, this tree has been laid aside in favor of the fig, which, it is believed, will make a good boundary belt. Wood and bamboos for purely building and agricultural purposes are freely obtained and largely purchased by the villagers. Three hundred acres of teak and sandal wood were planted out in one division alone, and are doing well, while in others similar experiments proved unsuccessful, the best results having been obtained where close planting was tried. By close planting is meant 9 feet by 9 feet, thus giving 538 trees to the acre. When the branches touched, every alternate tree was removed, and this plan was found to give better results than the old one of planting out at first 25 feet by 25 feet or 70 trees to the acre. Doubtless the close planting had an influence in preventing the growth of brushwood and under jungle, which is often fatal to young saplings. Contrary to the experience of the Forest Ddepartment elsewhere, the financial results are eminently satisfactory. This is owing to the valuable nature of the timber sold, a large proportion consisting of sandal-wood. The receipts amounted to Rs. 4,52,575, which, after deducting expenses, left a net revenue of Rs. 2,54,555. Of the gross income no less than Rs. 3,65,188 are due to sales of sandal-wood. Now that the time of restoration of this province is so near at hand, it were well if all the other departments could show such a clean bill as can the Forest Department.

FOSSIL FORESTS IN AMERICA.

IN the valley of the East Fork of the river which flows through the wonderful Yellowstone National Park of the United States, the group of rocks known for want of a better designation as the "Volcanic Tertiary," is typically developed, and has a thickness of upwards of 5,000ft. Its prevailing materials are fragmentary volcanic products, which have been apparently redistributed by the agency of water, and now form breccias, conglomerates, and sandstones. These strata contain a great abundance of silicified wood; and in many places trunks of trees many feet in height and of gigantic proportions seem to stand in the identical strata in which they grew. Sometimes the crumbling conglomerates wither away from about these, leaving them to stand upright along the steep mountain sides. Mr. W. H. Holmes gives an account of these forests in the recently published number of the 5th volume of the "Bulletin of the United States Geological and Geographical Survey" (Washington, February 28, 1879). A section is given representing the north face of Amethyst Mountain. It includes 2,000ft. The summit of this mountain is 9,400ft., above the sea, and the river flowing at its base is 6,700ft., over sea level. Riding up the smooth river-bed, one has but to look right up the cliffs to discover multitudes of the bleached trunks of these ancient forest trees. In some of the steeper portions of the mountain's face rows of upright trunks stand out like the columns of some long since ruined temple. On the more gentle slopes lower down, but where it is still too steep to support vegetation, save here and there a few pines, the petrified trunks fairly covered the surface, and were at first taken to be the shattered remains of a quite recent forest. Sometimes the trunks were found in a fine state of preservation. Some, lying prostrate, measured 50ft. to 60 ft. in length, and not a few of those were 5 ft. or 6 ft. in diameter. One indeed was found on careful measurement to be 10ft. in diameter. The woody structure was so well preserved that it could be at once declared this giant tree was not a conifer. The strata also contain, as might be expected, many rootlets, leaves, and fruits, a collection of which have been submitted for determination to Professor Leo Lesquereux. They include an Aralia, a Magnolia, and new species of a lime, an ash, an elm, and a diospyros; also some new ferns. Some of the species are apparently identical with those described by Professor Whitney from the Elk Creek strata. But these strata are lower than the Yellowstone Park strata by fully 1,000ft., and are separated from them by 15 miles of broken country. These extraordinary fossil forests add one more to the noteworthy objects to be found in the National Park of the United States, already in respect of its natural phenomena without an equal in any part of the world.—*Times.*

THE USES OF FORESTS.

STRANGE as it may seem, there are people who still doubt, if they do not positively deny, the close connection between forests and the moisture of any particular region. For the benefit of these sceptics, we purpose to glean a few facts from a chapter on Forest Royalty in Mr. Baring Gould's instructive work on "Germany Past and Present." He points out that forests are to Germany what the ocean is to the British Isles. The tendency of forests is to lower the temperature by day, and raise it during the night. In treeless wastes, such as a large portion of Russia, the changes of temperature are rapid and excessive, a fierce summer heat following directly upon the intense cold of a long winter. The German vineyards exist only through the protection afforded by the woodlands which fence in the Rhine valley. The influence of trees upon the rainfall is still more remarkable. On an open surface the water pours down in a cataract, and runs away to waste, being unable to penetrate the hard sodden surface. Trees, however, intercept the downpour, and allow the moisture to trickle slowly and gradually into the vegetation beneath them, which holds the precious liquid, and shield the earth from over-hasty evaporation. The water thus gently percolates through the surface-soil, and feeds the springs. On the Tuniberg, a range of hills near Strasbourg, gifted with a peculiarly rich soil, the peasants cut down the trees which seemed to interfere with the cultivation of their little plots, and, in consequence of their folly, the springs have dried up, and during the summer much damage is done by drought. So also in the Island of Ascension, Some years ago copious showers refreshed the drooping vegetation, till the residents in their unwisdom, cut down all the trees. The rains at once ceased; but, now that fresh plantations have been made, a sea-drizzle has begun, and, as the trees grow up, the clouds will yield their moisture. A belt of trees is further efficacious in breaking the force of the wind, as is shown between Calais and St. Omer and a low sandy ridge, clothed with firs and oaks, about three miles from the sea and running parallel with the coast. On the one side is to be seen a dreary expanse covered with rank grass, and on the other luxuriant crops and trees bending with a rich weight of fruit. Again, along the shores of the Baltic, from Memel to Kiel, a thick forest once screened Poland, Silesia, and Prussia from the biting east winds, as injurious to vegetable as to animal life. The Jews purchased the estates of the needy Polish nobles, and felled the timber for which there was a great demand in England, the result being the reduction of large tracts of fertile land to a sandy desert, and on the Lower Ems the sand advanced some thirty feet every year. It is further related how Frederick William I. cut down a belt of pines between Dantzig and Pillau, and sold the timber for 200,000 thalers. The strip has lately been replanted, but as yet the partially restored barrier is powerless to arrest the billows of sand which are fast filling up a large, lake and impeding the water communication between Elbing and Pillau and Konigsberg. Similar effects were produced in Prussian Saxony near the town of Duben by the reckless clearing away of the forests fifty years ago. The sand waves immediately swept over the corn fields, submerged the gardens, and were fast turning the pastures into a desert, when the forester of the district stepped forward to the rescue, and upreared a barrier of acacias, pines, and birches.

In mountainous regions the peasants often fire a hill-side of forest to obtain pasturage for their flocks and herds, and for a few years the experiment appears to succeed. By degrees the tree-roots rot away, and loosen their hold of the soil, which slides off beneath the torrents of melting snow. As the rocks become bared, the cattle and sheep cease to find nourishment, and the latter end of their improvident owners is worse than the first. In Austria and in Switzerland this practice is still of common occurrence, but a wiser system prevails in the Bavarian Alps. In the middle ages kings and great barons forbade the cutting down of forest trees, but from purely selfish motives, and in order to preserve game. With the increase of the population, and the growing power and wealth of the towns to whom the impoverished nobles were glad to sell their forests, clearings were made without forethought or discretion, until the local princes were compelled to intervene, and restrain the arm of the woodman. Under the French Republic whole forests disappeared, the peasants paying off their debts, and making a little purse for themselves by felling both private and commercial woods. In the twelve years between 1791 and 1803, three million acres of woods had been devastated, and further destruction was only arrested by Napoleon issuing a prohibition against the rooting up of woods for 21 years. The recent destructive floods at Bordeaux have been clearly traced to the denudation of the high lands whence spring the rivers that water that country. The ancient forests held back in reserve the downfall of water, but since the hills were bared of trees, grass, and soil, the rain water has rushed off in raging torrents, causing rivers to overflow their channels, and spreading desolation for miles around. Of late years the Prussian Government have made great efforts to redeem their past negligence. Since 1857 ten thousand acres of moorland have been annually planted, and the science of forestry and arboriculture is nowhere carried to such a point of perfection as in Germany. So numerous are the foresters that they support thirteen newspapers and periodicals, two of which are illustrated. Three calendars are specially published for their benefit, and in the last three months of 1878, no fewer than twenty-three works were published in connection with forestry and the chase.—*Madras Mail.*

GARDEN.

THE ORANGE.

THE orange is the longest lived fruit tree known. It is reputed to have attained the age of three hundred years, and been known to flourish and bear fruit for more than a hundred years. No fruit-tree will sustain itself and produce fruit so well under neglect and rough treatment. It begins to bear about the third year after budding, and by the fifth year produces an abundant crop, though the yield is gradually increased by age and favourable circumstances. The early growth of the orange is rapid, and by its tenth year it has grown more than it will in the next fifty, so far as its breadth and height are concerned ; but it is age that multiplies its fruit stems.

COFFEE.

MOZAMBIQUE COFFEE.

A RAMBLING correspondent of the *Madras Times* writing from the Malabar Coast, furnishes a few items of information in reference to cultivation in and around Cochin, which are not without nterest. He mentions amongst other things, that, though a general belief is entertained by professional planters in the difficulty or impossibility of growing coffee below a certain elevation, he saw growing on the plain north-west of Palghaut, trees large enough to admit of his conveniently walking under, and in full bearing of, what appeared to be a perfectly healthy crop. He mentions also having seen the same thing in the same neighbourhood at but a slightly increased elevation, and seems to think this attributable to the soil in those parts being alluvial. We are the more inclined to think these instances, no unusual exceptions, as, upon the island of Ibo in the Mozambique channel, where coffee grows *spontaneously* and in great abundance, it is found at but a trifling elevation ; and though small and of very inferior appearance, it is probably superior in flavour to any other coffee grown. This wild coffee is regularly gathered, but the quantity serves only to meet the demands of Mozambique, Zanzibar, and some few other markets on the East Coast of Africa.—*Bombay Review.*

COFFEE PROSPECTS IN CEYLON.

THIS subject has the most intimate bearing on the question of estate valuations which we discussed on a former occasion. Will plantations in the older, and for that matter in the young, Kandy districts ever regain their former vigour ? We believe many merchants and planters are considering this question at the present moment, and that some influential members of the community are inclined to answer it in the negative. Such a decision is, of course, injurious to the great planting enterprise, and, if promulgated without special qualifications, it can be shown, we believe, to be contrary to reason and experience. We leave out of view entirely, in our present remarks, the factor of "new products," although, as our readers are aware, there is now luckily no district in the country, if, indeed, there be many plantations, on which some attention has not been given to cinchona, cacao, tea, or cardamoms. This fact necessarily carries great influence in attempting any forecast of our planting enterprise. The contrast between the Dumbara valley of the present day and the same district ten years ago, we recently instanced as a case in point. Three thousand acres of cacao divided over the previously existing cultivated area have entirely changed the fortunes of most of the Dumbara properties, and the same result has been experienced in several other old districts. But, if we consider coffee alone, there are undeniable facts which serve to shew how rash and unfair might be a sweeping condemnation of old districts and plantations. The Dumbara valley itself includes some of the oldest coffee in the Island, and, we believe that last year the area cultivated—including all between the Hewaheta range on the one side and that of Rangala and Hunasgiriya on the other, up to an elevation of 2,000 and 2,500 feet,—gave a better crop than most other districts in the Island, and an outturn considerably above the average. It is quite evident that no "cut and dry" answer can be given to the question as to whether it is possible old estates should ever regain anything approaching their former condition. So far as we can judge from the history of agriculture and of the world, there is nothing to prevent their restoration to as much of their former vigour as is compatible with their increased age. To the sweeping question now locally propounded we might well reply with another and ask if our critics believe that farms in England will ever regain their former vigour, or that rust will exterminate cereals in Queensland and South Australia, or that the vines in Europe are doomed. We do not see why the enterprise in coffee should be any exception to the rule which applies to agriculture generally. It is impossible to venture on a safe opinion in respect of the future which is not, more or less, based on the experience of the past, and if we apply this rule to the case of several of our old districts and not a few plantations now under a ban in some quarters, we confess that we cannot see in them anything so exceptional as to doom them to a permanence of failure, or to distinguish them altogether from other depressed agricultural interests. If such interests are to recover in other lands, where depression has long prevailed, so ought judiciously cultivated coffee in Ceylon. The swing of the pendulum will undoubtedly come for those who may weather the present financial storm, and our fear may shortly be lest that swing of prosperity should once more carry the pendulum too far and revive extravagance, personal habits, careless management, over speculation, or neglect of prudent financial arrangements.—*Ceylon Observer.*

MYSORE PLANTERS' ASSOCIATION.

AT a General Meeting of the Mysore Planters' Association held at Sucklaspore, on Monday, the 24th May 1880, the following circular was read :—

Circular.—The undersigned have the honor to invite the co-operation of all Mysore planters in endeavouring by practical experiment to arrive at some definite conclusion as to the most feasible method of mitigating the ravages and effects of leaf disease and " rot" in coffee.

Parasitic disease, its origin, development and cure, is doubtless a profound subject, but ruinously influencing as it does the enterprise in which all planters are so deeply interested, it is earnestly hoped that many may be induced to assist in collecting information in connection with well conducted field experiments.

It is suggested that an accurate record of all experiments should be forwarded to the head-quarters of the Association together with any information or suggestions which may appear likely to be of any practical utility.

A committee of planters will be subsequently formed to consider the subject generally; and draw up a report embodying the information obtained.

In addition to research in regard to cause and effects, the collection of reliable information on the following points appear to be highly desirable.

1. The effects of various measures for improving the mechanical condition of the soil.
2. The effect of various manures.
3. Experiments in connection with handling, pruning, &c.
4. Shade and its influence.
5. Observation regarding the physical and mechanical condition of soil.
6. The influence of rainfall and peculiarities of climate.
7. The management of nurseries, embracing the result of experiments with imported and acclimatized seed; the effect of irrigation shade, and forcing applications, together with remarks as to the possibility of spores being transmitted in the mucilage of badly prepared seed.
8. Analysis of soils—chemical and mechanical, including research in regard to any abnormal peculiarities either original or acquired.
9. The mitigating or curative powers of lime, sulphur, potash, magnesia, petroleum, salt, soot, Condy's fluid, &c.
10. Root pruning its effects and management.
11. The effect of stem cleaning and application of various washes such as :—
    - *a.* White wash.
    - *b.* Wash composed of lime, sulphur, and cowdung.
    - *c.* Petroleum.
    - *d.* Carbolic acid.
    - *e.* Permanganate of potash.
    - *f.* Chloride of lime.
12. The effects of deep cultivation and sub-soiling.

CINCHONA.

A RECENT *Gazette* contains a resolution on the annual report of the Cinchona plantations in Sikhim for the past official year. The season appears to have been unusually favourable and about three-quarters of a million of young trees were planted out, of which 644,222 were *Succirubra*, against 353,415 planted in the previous year. The efforts made to propagate the *Calisaya* and hybrid varieties have at last begun to bear fruit. Of the latter, 76,080, and of *Calisaya* 12,782 were planted during the year. The entire produce of the year was 361,590lb. of dry bark against 261,659lb. in 1878-79 ; making the total produce of the plantations since their opening 1,496,491 lb. 14,240 lb. of the yellow or *Calisaya* bark were sent to England for sale towards the close of the year, but, as Mr. Gammie has now succeeded in making sulphate of quinine of excellent quality from this bark, it will probably not be desirable to send any more away. The total outturn of the febrifuge factory for the year was 9,434 lb. against 7,007 lb. in the previous year, and the sales to the public exceeded those of 1878-79 by 358lb., a circumstance which proves that the drug is rising in general estimation. The result of the operations, from a financial point of view, continues to be most satisfactory. Calculating the average price of quinine in Calcutta at Rs. 90, the total saving effected by the substitution of the febrifuge for the former drug in the Government hospitals and dispensaries since the factory commenced working, aggregates 11¾ lakhs, or more than the plantations have cost since they were opened. The proposal to erect a small factory for the manufacture of pure sulphate of quinine is now under the consideration of the Government of India.

RELATIVE MERITS OF CINCHONA ALKALOIDS (OTHER THAN QUININE) AND THE SIKHIM MIXED FEBRIFUGE.

PREVIOUS experiments made in the Indian hospitals having proved that cinchonidine and cinchonine were very little, if at all, inferior to quinine in the treatment of fevers, comparisons have now been instituted between those separate alkaloids and the Sikhim febrifuge which contains *all* the alkaloids of red bark in certain fixed proprotions, quinine, if we remember rightly, constituting 16 per cent. of the whole. All attempts to obtain a mixed febrifuge in the Madras Presidency were abandoned because a Commission reported that Mr. Broughton's mixture cost far more than the price at which sulphate of quinine could be purchased. Mr. Broughton, therefore, in very indecorous terms, as is evident from the minutes recorded by the members of the Madras Government, resigned his appointment and disappeared in a manner so sudden and mysterious that he was long supposed to be dead. It is now certain, however, that he went first to England and then to New Zealand. In the case of the British Sikhim bark, there appears to be much less waste, although there is still a considerable percentage lost. The Bengal Government, with the sanction of that of India, no doubt, have consented to look, not at the price which the bark might fetch in the markets of the world, but at the cost at which it is produced. In this way the febrifuge can be sold to the public at about Rs. 2 per lb. Waving the question of real cost, the object of recent experiments has been to compare the effects of the mixed febrifuge, into which quinine, quinidine (very little), cinchonidine, and cinchonine are combined, with those of the two latter alkaloids in their separate state The Surgeon-General of the India Medical Department has reported the results of the experiments in a paper which we quote as follows:—

The results of the trials are given and con trasted in the following table, but the comparison is not quite a fair one, as there were so many more cases of fever treated by Sikhim febrifuge than by either of the two other remedies:—

Preparations.	Average Dose.	Average quantity given in each case.	Average No. of days each case.	No cases treated.	Cured.	Died.
	grs.	grs.				
Sul. cinchonidine ...	6·24	87·93	5·86	970	849	...
„ Cinchonine ...	9·52	109·57	6·55	917	805	8
Sikhim febrifuge ...	7·66	80·78	5·46	3,198	2,915	18

It appeares that a less quantity of the Sikhim febrifuge was required than of either cinchonidine or cinchon ine to cure an attack of fever. The actual average quantity used of each febrifuge was as follows:—

	Grains.
Sikhim febrifuge	80·78
Sulphate of cinchonidine	87·93
Do.	109·57

From these figures it appears that the Sikhim drug is the most active of the three, sulphate of cinchonidine the next active, and sulphate of cinchonine the least active as a febrifuge.

The Sikhim febrifuge had also the advantage as regards the time required to effect the cure of a paroxysm of fever—a point of great importance as regards the soldier, and also as regards some of the labouring classes. The following are the figures:—

	Days.
Sikhim febrifuge	5·46
Sulphate of cinchonidine	5·86
Do. of cinchonine	6·55

In this respect also, therefore, the three preparations hold the same relative positions.

The relative curative merits of the three drugs as shown by the figures given above in paragraph 5 may be illustrated as follows:—

Preparations.	Rate per cent. of. Cured to treated.	Not cured to treated.	Deaths to treated.
Sikhim febrifuge ...	91·15	8·44	·40
Sulphate of cinchonine ...	87·78	11·38	·82
Do. of cinchonidine ...	87·53	12·47	—

This places the Sikhim febrifuge first on the list as a febrifuge, cinchonine next, and cinchonidine lowest. These results are somewhat unexpected, and must not be regarded as final. Further experiments are in progress, and in due course the available data will be sufficiently numerous to indicate authoritatively the respective merits of the three preparations. The unpleasant effects caused by the Sikhim preparation were marked, and still form the chief obstacle to its more extended use. The superior position of the Sikhim febrifuge is possibly due to the proportion of quinine it contains, and Dr. King holds strongly that if the doctors gave up the idea that larger doses of the febrifuge are required, than of pure quinine, the symptoms of giddiness and nausea (with vomiting and purging) now complained of, would not occur so frequently. Even quinine occasions symptoms of giddiness and nausea in some cases. Giddiness is an unpleasant symptom, but not likely to do much harm, which nausea and its results in cases of fever may be positively curative. As this is the first report in which cinchonine has, *in any respect*, taken a place before cinchonidine, the Surgeon-General does quite right in asking that the result of further experiments should be waited for. At present the main alkaloids take rank thus:—

No. 1	Quinine.
„ 2 (but closely approaching No. 1) ...	Cinchonidine.
„ 3	Cinchonine.

The mixed febrifuge stands by itself, and can, at present, be purchased at as low a price as even cinchonine could be laid down in India. For Government hospitals, coolies' line, &c., therefore, nothing better could be used, specially if a solvent is employed, or the febrifuge made up in the form of pills. Before Mr. Wood was compelled to resign his appointment, the idea of separating the alkaloids was entertained in Bengal, and after all we suppose this will be ultimately done in view of the waste of at least 2 per cent. of alkaloids by the present process. The home manufacturers use apparatus and have secrets by which it is said every trace of alkaloid is extracted. The value of the Messrs. Howard's plant is valued at £100,000. All attempts to manufacture alkaloids in South America have failed. So with Mr. Broughton's experiment in the Madras Presidency. If the Bengal experiment, therefore, proves finally successful on every ground, commercial as benevolent, it will be unique in the history of the fever barks. In any case, it has provided a cheap febrifuge for a population who are specially liable to attacks of malarious fever.—*Ceylon Observer.*

MR. MOENS ON CINCHONA CULTURE IN JAVA.

THE *Ceylon Observer* gives Mr. Moens' replies to the circular it issued some time ago, and says, "from the interesting and valuable information afforded, our readers will gain fresh evidence of the effect of the rich soil of Java on the fever plants. The Nilgiris, British Sikkim, and Ceylon are left far behind when the best growths are compared with a *succirubra* tree of 14 years old, 68 feet high, and 3½ feet in girth; a *Calisaya* tree 17 years old, 60 feet in height, and 3 feet in girth; and a *Ledgeriana* 13 years old, 48 feet high, and 3 feet in girth. It is only the richest soils of Uva which can possibly give results to compare with these. From Mr. Moens' replies it would appear that no cinchonas, not even *succirubras*, are cultivated in Java (at least on Government plantations) below 4,000 feet, the range for *succirubra* being 4,000 to 5,000 feet; that for Ledgeriana from 4,000 to 5,000; while in the case of *officinalis* the lowest limit is 5,000 feet and the range up to 6,000. We suppose that in truth, 8,000 might be safely substituted for this latter figure, even if it should turn out to be true that the Java climate is so much colder than ours."

BANDONG, 1*st May.*—With this post I will send back the questions, answered as far as possible, without writing a book about them all. The question about harvesting is particularly difficult not only which is the best mode, but also how great the yield of the trees is. On 8½ bouw of Ledgeriana has given, within 13 years till now, 34,019 half kilogrammes, say 38,080 E. pounds, by thinning, coppicing, and scraping. And if you saw the gardens at present, you would ask where this bark had been taken? as the plantation is quite close and regular. We took only what was too much, and would hinder the growth of the finest trees. I have just had the pleasure to make the acquaintance of Messrs. Alexander and Kay Shuttleworth. They saw also the Ledgeriana plantation and agreed that it is not to be seen, where this quantity of bark, amounting to about 2,573 E. p. per acre, has been gathered. I am sure that the trees and shoots now left in these gardens, when uprooted, would give easily another 4,000 E. p. per acre.

But it is not always so good. I have just uprooted a piece of *C. officinalis* plantation, planted at 4,200 feet, *i.e.*, too low, and damaged since 4 years by the tea-bug (*Helopeltis Antonii*). From 80,000 trees, planted out in 1873 and 1874, I got about 1,000 kilogrammes of bark. This is a failure, but, if you get the tea-bug, such things may happen; and, as tea cultivation is spreading over Ceylon, I fear you will not escape this worst of all cinchona plagues. I often had caterpillars in the gardens, but do not care for them, as they do no serious harm, but these bugs make a fearful pest, and we could never get rid of them. In some plantations, in the dry season, when they appear to come in the greatest quantity, a young garden often looks as if boiling water had been poured over it, and it takes two or three months before the trees have recovered. These little creatures check our success, which would be too great without them, perhaps. It is a comfort that I may remember that it has been even in these 8½ bouw orig. Ledgeriana, the bug appeared first and that they have since often been severely damaged by them.

I saw from the last *Observer* that you had received the sad tidings of Scheffer's death. My lamented friend died from an inflammation of the liver. We thought he was on the way of recovery; he had been transported to the hills, but suddenly he collapsed and died quite unexpectedly. It is a heavy loss, not only for us and for our country, but for the science, botanical and agricultural, for the whole world, and it will be very difficult to fill his place. Scheffer was a young man, about 33 years old, and, with the zeal and science and active power he displayed, could have produced an immense deal of noble work. It is a great pity indeed.

As I am not directly connected with the Botanical Garden in Buitenzorg, this will not interfere with my going to British India and Ceylon. I intend to go there in August next, leaving Batavia with the French mail of

the 18th of that month. I can then be in Ootacamund about the middle of September, when they are barking there, and in November in Br. Sikhim. I thought first of coming in March, but Mr. Money warned me not to go to Bengal between March and September, as the dreadful heat would be almost unbearable, and would prevent me from seeing Agra and Delhi, without danger to my health. I could perhaps have found a better time to come to Ceylon, but it is difficult to be everywhere in the best season. I hope to see you, and will be sure to call at Abbotsford.

The rains continue as fast as ever, and we have now a wet monsoon, lasting about 1½ year I hope it will soon change, for if we get no regular dry season, the Ledgeriana trees will never flower, and the seed crop fail again. You remember perhaps that Mr. Ledger—or rather Mr. Ledger's servant—said that the trees, from which the first seed was taken, had not flowered since four years, on account of frost killing the flowers. But I think the reason will have been that in these dense forests frost would be so severe as to destroy the flowers. And the cinchonas do not flower in the dry season when cold is most severe, but one or two months after the rains set in.

What Mr. Howard says about the British and Dutch Government refusing to Ledger the slightest compensation for his losses (*Pharm. Journ.* 13th March) is not quite right. Ledger has a very slight part in the whole business. The seeds have been gathered by an old servant of his, whilst he was on his travel back from Australia to Peru. The man brought the seed to the coast where Ledger was, and will have received a very small pay for it. It is a pity that this poor fellow has been killed for this reason (if it is true?) But I think that, for an Indian, he could have given his life for a worse cause, and without becoming an immortal hero in quinology. Who would know the name of Manuel Incra Mamani if he has not been so happy as to find the true Ledgeriana,—bringing it to Ledger?

I have a letter of Mr. G. Ledger (C. Ledger's brother) before me, copy of a letter of him to our Consul in London, Mr. May, dated 30th October 1865, in which he writes :—" As near as I can make out of 100 (about eight pounds st.) is just about the proportion of *cost* to the quantity of seed I have." When the seeds had germinated, Ledger received again 800f. (in all £50) and he then wrote (9th January 1861) :—" I also feel bound to express my sincere and hearty thanks for the prompt and generous manner in which your Government has responded to the condition suggested by me as to future reward," &c. In 1871 Ledger offered to procure seeds *on the same conditions as in* 1865, a further proof that he thought he was well paid for the part he took in the business. So when he, knowing the high value of C. Ledgeriana, came in 1876, with a claim for further payment to the Dutch Government, they could not find terms to reconsider the business, which had been concluded on fair terms and the greatest contentment of both parties, ten years before. Now Ledger complains very much (in his letter of Nov. 3. 1875) and says that "his brother G. Ledger received only 600 guilders, when he had expended more than as many pounds in its acquisition." If you consider this claim, in connection with the formers letters, before L. knew that C. Ledgeriana was so good a kind, you may conceive what we had to think of his arguments and lamentation.

My government, though not being in a position to acquiesce to L.'s claim, was very willing to give him a reward in another form, and authorized me to enter into a proposition of Ledger's to procure us a new supply of seeds, and to pay it very liberally. I wrote to Ledger (though I doubt his faculty of getting true Ledgeriana seed, because he does not know where to find them), but never received an answer.

If cinchona growers would make a statue for the clever cascarillero, Manuel Incra Mamani, some reason could be found from that. But Ledger has indeed only a very small part in the history. and procured the seed without, danger, and without trouble, and without knowing indeed that he had got hold of such a precious kind of seeds. And the *British* Government has nothing at all to do with it, for it was not the Government that bought the remainder of L.'s seeds, but our friend Mr. Money and he paid quite the same amount for it as we did.

Elevation?—Mr. Moens : 4,000 to 6,000 feet. [Mr. Rawson : 6,000.]

What species and varieties grow best with you?—Succirubra from 4,000 to 5,500, Ledgeriana from 4,000 to 5,000, Officinalis 5,000 to 6,000 feet. [Mr. R. : Succirubra and Officinalis.]

State age of trees, and extreme and average dimensions.—Trees from one to 24 years; tallest trees succirubra of 14 years : 65 ft. high, 8½ ft. girth ; Calisaya 17 years, 60 ft. 8 ft., girth ; Ledgeriana 13 years, 48 ft. to 3 ft. girth. [Mr. R. : 10 at 18 years, respectively (extreme), 30' × 1½ to 3 ft. average 20ft. × 1—extreme 40' X 37"—average 26 ft. X 24 inches.]

What is the yield of trees by any method of harvesting you have employed?—The highest amount has been from an uprooted Hasskarliana of 17 years which gave 95 pounds of dry bark. Average two (officinalis) to four (Ledgeriana) or six (succirubra) pounds after eight years (uprooted) [Mr. R. : 14 years old trees coppiced averages 4¼ lb., 17 years old stripped averages for 7th time 41-10th lb., good total 18½ lb. without branch.]

Do coppiced trees send up healthy shoots? And state whether the stools were left under shade of surrounding trees, or thoroughly exposed.—Yes, always thoroughly exposed, if succirubra. Officinalis and Ledgeriana may be coppiced in alternate rows if planted : officinalis at 5, and Ledgeriana at 6ft. [Mr. R. : Yes : thoroughly exposed.]

Have you found the bark renew freely after partial stripping?—Yes but there are always failures, specially at the borders of the gardens : [Mr. R. : Yes.]

Has the operation affected the growth of the trees?—Not till now, has been applied since three years. [Mr. R. : I think not.]

Have you tried covering the wound with any other material than moss; and with what results?—Use often *indjoca*, a fibrous substance from the sugar palm (*Arenga saccharifar*), with excellent results. [Mr. R. with grass. Renewal, so far, as good as if moss have been used.]

Have you tried the system of shaving off the outer bark, leaving the liber intact? And with what result? Yes ; the bark regenerates very soon in all species. No deaths. Not yet known whether the quinine increases. [Mr. R. : Not yet.]

What diseases have effected your trees? Our trees are affected by the *Helopelt Antonii*, a bug, which gives much trouble and damage. Canker very rare [Mr. R. : Canker to a small extent only.]

Have you any remedy to suggest for them?—No [Mr. R. : Cover with moss.]

Have you found canker proving fatal the exception or the rule?—Canker very seldom seen. Not fatal. [Mr. R. : No, with few exceptions, our canker as a rule affect only one side of the tree].

Have you tried manuring, and with what result—Have tried manure. Compost only (cow and horse dung, &c.) Trees grow luxuriant. Analysis about amelioration of bark cannot yet be relied upon. [Mr R. : Yes, with good results in expediting renewal and increase of thickness of bark ; also increased foliage of darker color.]

Have you reason to suppose that trees from cuttings are less healthy than those from seed?—No. [Mr R. : No, I much prefer seedlings.]

Have you tried cinchona on patana land, or amongst old coffee, and with what results? Yes; grows well if the sub-soil is good ; requires high cultivation. [Mr, R. : On patana land largely with very good results : officinalis more successful than succirubra.]

Is sporting less common amongst plants from cuttings than from seeds? If so, is the difference large or not?—Cuttings do not sport. [Mr. R. : Cannot say, as our propagation is almost entirely from seed.]

Give any analysis of bark from the large leaves variety of officinalis ; stating, if possible, the yield of bark per tree and its age?—Contained quinine 1·8, cinchonidine 4·82, cinchonine 0·79, amorph, alk. 2·09. Three of eight years. (This means a large, rapid growing kind, probably a hybrid.—Ed.) [Mr. R. : Quinine 8·53, Quinindine 0·08, Chinchon, 1·33, Chinchonine 0·20, Crystall, sulphate q. 4·75. Aged 16 years.]

SERICULTURE.

COLONEL COMBER, the Deputy Commissioner of Durrung, reports that imported cottons are rapidly driving the local silk manufacture out of the market. That this should be so is inevitable, though a matter for regret. If the indigenous silk ceases to be manufactured in the district, there is at least some prospect of its finding a profitable market in Europe where the wild silks of India (among which the *Eria* and *Muga* silks of Assam hold a high place) have recently been attracting much attention.

THE *Fiji Times* has received a sample of product called Kapok, for which it appears there is a remunerative market open in the colonies. The substance is of the texture of silk, but very short and weak in the staple. It is the product of a weed which grows abundantly in many parts of Fiji, and the fact that the substance has a recognized commercial value, may, it is said, serve to make the obnoxious presence of the parent stem the more readily tolerated.

THE INAUGURATION OF AN INDIAN SILK INDUSTRY.

BY invitation of Mr. Lepper, the Managing Director in India for Messrs. Lister & Co., of Bradford, in England, who have recently established a silk-growing business at Dehra and in the Gurdaspore district in the Punjab—our correspondent proceeded on the 22nd ultimo to Kaulagir, to witness the payment of the prices of cocoons reared this season by those to whom seed had been distributed, and the award of prizes for the season's results, and to hear the announcement of prizes to be given for the future. There were present the European managers of several tea plantations in the neighbourhood, who had interested themselves in the matter chiefly for the sake of setting an example to the natives, and also partly with the view of observing which species and varieties of the mulberry plant seemed to yield the best food for silkworms. One of these gentlemen said that his cocoons had yielded him cent. per cent. for his outlay ; but then he had not had to spend anything on rearing-sheds. All were, our correspondent believed, satisfied that they could make silk-rearing pay well. The principal native present was the Mahant,—a Hindu high priest,—of Dehra, who, as a landowner, had reared some good cocoons, and who seemed much interested in the proceedings. And there were some twenty or thirty native zemindars and rayats who had taken part in the season's work.

Mr. Lepper had prepared an address, a copy of which, in English, was given to the Europeans to read, and a translation in Urdu was read out. But, as Urdu is "not well understanded of the people," a Hindi translation of the address was, we understand, to be prepared and printed for circulation among them.

Mr. Lepper began by explaining to his audience that he had asked them to be present that day, not only that he might pay them the value of their cocoons, but also, and chiefly, in order fittingly to inaugurate and celebrate

an important step of progress which the district had now made. And he was further anxious that the cultivators should become thoroughly acquainted with the bright prospects before them, and with the plans he had formed for encouraging and assisting them in future.

Mr. Lepper then reminded the silk-growers what they owed to the perseverance and good will of the Superintendent of the Dun, Mr. Ross. Years ago that gentleman saw what a great advantage this climate offered to rearers of silk-worms, and, knowing well how profitable the industry had proved in other countries he saw how great a boon it would prove to the natives under his care. With this before him Mr. Ross had perseveringly followed on this idea, in the midst of his many other important duties, and notwithstanding frequent disheartening results. He had to teach himself, before he could attempt to teach others. He had total ignorance on the part of others, and prejudice against a new pursuit, to contend against. He had yearly pecuniary failure to explain to Government, whilst at the same time he had to appeal for funds for further trials. Confident, however, of the merits of his object, nothing daunted, nothing stopped him. In order to attract European enterprise, he proved the suitability of the climate for mulberry cultivation by planting these trees all along the roads and canals of the district. He sent samples of cocoons, reared by himself, to different experts for their opinions, and in order to create an interest in the work. And at last he succeeded in attracting the attention of a firm fully capable of giving the Dun every chance of success as a silk-rearing locality. This is the history of this new industry, now in their own hands and their success in future should always recall to their grateful remembrance the name of Mr. Ross.

Mr. Lepper had felt some doubts as to attempting to induce anyone to try the new industry under the present disadvantages of the leaf supply. He knew that the chief item of cost in silk-rearing was that of carriage of leaf, and that if sufficient leaf was not procurable close to the rearing sheds, four or even eight men, according to distance, might be required to pluck and bring it in, for one man that would be required were the leaf as close at hand as it should be. If, therefore, they should find their leaf supply failing in their own neighbourhood, and have to send to a distance for it, the experiment would then not have a fair trial. Still, after all, he had thought it would be better to make a start at once, and trust to the intelligence of those experimenting, to understand that a moderate success under the present disadvantages would show how much better the cultivation would succeed if they could reduce their distance from their leaf-supply. His fears about the leaf-supply had, unhappily, been satisfied. The roadside trees became too dusty, and some of the cultivators had been compelled to send carts miles, for leaf, thus spending, he thought, four times what ought to have been necessary. He was sure they understood this, from the conversations he had had with all of them. But notwithstanding this disadvantage, and their want of previous experience, he was quite certain that none of them had lost money that year. Experience was as important in silk-rearing as in ploughing; they had tried a new thing, and he must say their produce had not been wonderfully good; but they had shown a desire to succeed, and that desire, combined with more experience, would very quickly improve their results. This year, being anxious to encourage them as pioneers, in every possible way, he would make only one price for their produce, and pay all alike the full value of first-class cocoons, though with two exceptions—theirs were of a very low class indeed. After they had acquired more experience, he would make it worth their while to try and turn out first-class cocoons by offering prizes for the best, and by paying for the cocoons according to quality.

Mr. Lepper then proceeded to explain another branch of the silk industry, *viz.*, that of the castor-oil plant feeding silkworm. If this worm could only be acclimatised in the Dun, it would be a great boon to the poorer men amongst them. As they all knew, the mulberry tree took some years to come into bearing. They also now know that only one crop of silk could be got in a year from the mulberry worm. These two circumstances must tell very much against a poor man attempting to make a profit from growing mulberry. True—the mulberry silk was more valuable than the castor-oil fed silk, but the poor man would look at the time the mulberry trees took to grow, and at the fact of his rearing shed being empty for eleven months out of the twelve, and would feel disheartened; whereas a rich man could afford to wait for his mulberry trees to grow. To the poor man sowing castor-oil seed the future would be nearer; in two or three months he would have leaves, and if the Eria worm succeeded well in the climate of the Dun, as Mr. Lepper hoped it would, he would get four or five crops of cocoons in a year instead of only one.

As an experiment, Mr. Lepper had sent to Bengal for a seer of eggs, and they ought to arrive shortly. He should distribute these eggs in small quantities to cultivators owning castor-oil plants of a pluckable age, and who might desire to make a trial. And before that crop should have produced eggs in its turn, he trusted that a considerable area of castor-oil plant would be available. To give poor men a chance, he should be glad to give a reward of one rupee for every beegah of land having castor-oil plants properly planted on it for silk-rearing purposes, which plants must be five feet high in nine weeks from that day,—no man, however, to receive more than ten rupees.

Mr. Lepper then proceeded to announce his awards of prizes for the past season's experiments, and explained that, as the cocoons produced this year were so poor,—owing to the difficulty there had been in getting leaf, and the late date at which the eggs had been hatched, and the inexperience of the growers,—he could not give a prize for *quality*, except to one man. And indeed they were not independent rearers, for he had provided Cashmiris to instruct them. The one exception was a man at Ambiwala, who had reared the cocoons of one shed there quite independently of Cashmiri attention, and whose cocoons were yet decidedly the best of the year. That man, however, had had the great advantage of mud walls to his shed; and from this year's experience, he (Mr. Lepper) would advise all who could afford it to put mud walls to their sheds, for that made a difference of five to seven rupees per maund in the value of the cocoons. The Ambiwala grower would receive a watch, as the only reward given this year for quality. Indur Singh of Rangawala, having by his attention to the instructions for careful feeding produced the earliest cocoons should also receive a watch as a reward.

But, further, Mr. Lepper said he would present, to all who had this year acted as pioneers of the new industry, a silver medal. The fact that he was paying the growers about five annas in the rupee more than the market for their this year's crop, must also be considered as encouragement given. And Mr. Lepper intended also every year to set up a memorial stone, bearing a sculptured inscription, in the village which should have produced most silk during the year, on a site to be selected by the inhabitants, one stone for mulberry silk, and another for castor-oil silk.

Mr. Leppor then announced the prizes he intended giving for the future as follows:—

First competition.—*1st prize.*—A gold medal and Rs 200 for the best mulberry plantation according to his specification ready by 1st May 1883 *2nd prize*, a silver medal and Rs. 100.

Second competition.—*1st prize.*—Rs. 50, and a silver medal to the rayat who should on 1st May 1883 have on his land the most young mulberry trees of certain age and size; *2nd prize*, Rs. 25 and *3rd, prize*, Rs. 10.

Third competition.—*1st prize.*—A silver medal and Rs. 50 for the most land on castor-oil plant, really for silkworm rearing purposes, before the 28th November 1880; *2nd prize*, Rs. 40; *3rd prize*, Rs. 30; *4th prize*, Rs. 20; and *5th prize*, Rs. 10; no area under ten beeghas to compete.

Fourth competition.—*1st prize.*—A silver medal and Rs. 50 for the largest outturn by 30th November 1880 of castor-oil fed silk; *2nd prize*, Rs. 40; *3rd prize* Rs. 30; *4th prize*, Rs. 20; *5th prize*, Rs. 10; *6th prize*, Rs. 5.

Besides these, Mr. Leppor said that there would be prizes for next year's mulberry silk, the particulars of which he should publish later on. And he hoped that next year an exhibition of both kinds of silk would be held at Kauligir, at which the rearers should compete for prizes for quality. A list of the prizes he had now awarded and offered for future competition would be printed and circulated in the villages.

In conclusion, Mr. Lepper thanked all present for their attendance, and announced that rooted cuttings of the mulberry would be distributed *gratis* at the proper time, to approved intending growers.

We believe that the pruning of the existing mulberry trees on the Dun is now engaging Mr. Lepper's attention. This is an important point, for on judicious pruning depends the supply of good young leaf shoots next spring. The eggs produced this year are being kept, up at Mussoorie, till next spring.—*Civil & Military Gazette.*

TOBACCO.

THE PREPARATION OF TOBACCO.

IN two recent articles (see July number, ED., *I. A.*) we treated of the selection and of the planting of tobacco, it remains for us to describe the best method of preparing the leaf, before leaving the subject.

The leaf having matured, it is only necessary to cut down the whole plant with a long knife (wetta-catty) close to the ground. This can be done only in perfectly fine weather, and when the morning dew is upon the plant. A framework of posts and horizontals should be fixed up under any clump of shade-giving trees, and the plant tied together by plantain fibre in pairs, and gently placed, across the bamboos, which are in turn placed on the framework, so that the pendant plants do not touch the ground; in placing the plants on the bamboos, it is well to see that they are not pressed together; the frame-work should be large enough to accommodate one day's cutting; the plants should be left there until they are withered, which operation will probably take one day: care must be observed during the process that the leaves are not allowed to dry too quickly or they will become shrivelled and remain green. The withering being done and the leaves having acquired an old-rag-like feeling, the bamboos with the plants hanging upon them, are carried to the drying shed. Before we can state the drying process, it is necessary to describe the drying shed; we suppose that on each half acre plot of tobacco there should be built a shed 50 × 20 feet, but as the most temporary building will suffice, this need not prove a serious drawback. The walls of the shed should be 17 feet high, roofed with cadjan, and having shutters in three tiers, one above the other, and opposite each other, so as to regulate the current of air through the building; flush with the window heads of each tier should be erected frames to accommodate the bamboos upon which the withered plants hang. When there is a hot breeze blowing, the windows must be closed so as to avoid the danger of too rapidly drying. The plants should remain on the lower tier "close hung" until the leaves have turned yellow, which will be from six to ten days. They are next hung upon the upper tier, the windows opened and the plants "free hung," so that the air may circulate well around them

SEVEN PRIZE MEDALS AWARDED.

GOODALL'S HOUSEHOLD SPECIALITIES.

A Single Trial solicited from those who have not yet tried these splendid preparations.

Goodall's Yorkshire Relish

The most delicious sauce in the world; enriches hot joints, stews, chops, fish, &c.; with soup it is charming; blends admirably with all gravies; makes cold meat a luxury; makes the plainest viands palatable; the daintiest dishes more delicious; a great addition to cheese; every dish is improved by its addition; epicures pronounce it the best sauce; beware of colourable imitations.

CAUTION.—On each label is our Trade Mark, Willow Pattern Plate, and name, GOODALL, BACKHOUSE and Co. No other is genuine.

Whatever prejudice may have existed at any time on account of its cheapness has become entirely dissipated by the daily use of this really good sauce. We merely solicit a trial from those who have not used it, after which we feel confident they will use no other sauce.

Over four million (4,000,000) bottles sold annually. Largest sale of any sauce in the world. Sold by Grocers, Oilmen, Chemists, &c., in bottles, 6d., 1s., and 2s. each.

TESTIMONIAL.—"4, Wimbourne Street, New North Road, London, N., 18th May, 1875.—Gentlemen,—I have not the pleasure of knowing you—never met you, never saw you—but still for a great length of time my sideboard has never lacked your celebrated YORKSHIRE RELISH, and it gives me very great pleasure to forward this Testimonial in its favour, provided you think it worthy of your acceptance. My sedentary habits as a writer for the magazines, &c., very often makes me exceedingly peevish with my meals, but still, no matter what I have, your YORKSHIRE RELISH always brings me to. Sometimes I have a hot joint that it enriches, sometimes cold meat that it makes exceedingly tasty and palatable—with soup it is charming. And sometimes, when the press is waiting for matter, I can make a very good makeshift for dinner with a roll steeped in it; so that in each and every sense of the word I cannot speak too highly of that which I find so good, so useful, and so cheap. If it is likely to be productive of good you are quite at liberty to publish this. —Yours truly, the Author of 'Grace Darling,' 'Harriet Stanton,' 'The Wreck of the Royal Charter,' &c.—To Goodall, Backhouse, and Co., Leeds.

Goodall's Quinine Wine

The best tonic for invalids; the cheapest, because the best; invaluable for neuralgia; testimonials to its efficacy innumerable; pre-eminent for purity and strength; recommended by every one who has tried it; thousands benefited by its use; awarded seven prize medals.

Highly recommended by the most eminent physicians, and acknowledged to be the best and cheapest tonic yet introduced. Strengthens the whole system, and stimulates the appetite. It is invaluable for Indigestion, Nervousness, Gout, Rheumatics, &c. Has proved an invaluable and agreeable stomachic to all suffering from general debility and loss of appetite. The best restorative for the weak, young, or aged. Is admirably adapted for delicate children and persons to whom quinine in any other form is objectionable, and is especially suited as a vehicle for the administration of Cod Liver Oil where the combined effect of Quinine and of the *Ol. Jecoris Aselli* is desirable. A wineglassful twice or thrice a day will be found both grateful and efficacious in all cases in which a cordial tonic is required—far superior to sherry and bitters or bitter beer.

[TESTIMONIAL FROM MISS EMILY FAITHFULL.]

"Victoria Press, 85, Praed Street, London W., 20th August, 1874.

"Dear Sirs,—Having tested your excellent Quinine Wine, I am only too glad to testify to its efficacy in neuralgia, &c., as a certain cure and preventive, which is better than cure.—Yours truly, "EMILY FAITHFULL."

Sold by Grocers, Chemists, Patent Medicine Dealers and Confectioners, in Large Bottles, at 2s. each.

Goodall's Brunswick Black

For painting stoves, grates, iron, tin, &c. This invaluable composition is superior to any yet offered to the public, possessing great brilliancy, and thoroughly protecting the article it is applied to.

Sold in bottles at 6d. and 1s. each.

Goodall's Mushroom Ketchup

This splendid speciality is confidently recommended to all true lovers of the pure mushroom. It is prepared with the utmost care from the PURE JUICE, by a special steam process, secured at great cost by the proprietors, unrivalled for producing a ketchup uniform in strength, with a FULL AND RICH FLAVOR unpossessed by any other preparation of its kind in the market. One trial is sufficient to convince all of its great strength, perfect purity, and unsurpassed flavor. Sold in bottles at 6d., 1s., and 2s. each, by Grocers, Oilmen, and Italian Warehousemen all over the kingdom.

Goodall's Baking Powder

THE BEST BAKING POWDER IN THE WORLD.

Warranted Pure, Free from Alum, and all other Injurious Ingredients.

AWARDED SEVEN PRIZE MEDALS.	MANUFACTURED FROM THE PUREST INGREDIENTS.
UNRIVALLED for EFFICIENCY and PURITY.	TESTIMONIALS INNUMERABLE.
RECOMMENDED by ALL WHO HAVE TRIED IT.	DISPENSES WITH BREWERS' YEAST.
DEFIES COMPARISON	GIVE IT A TRIAL.

The cheapest because the best; indispensable to every household; and an inestimable boon to housewives. Makes delicious puddings without eggs, pastry without butter, and beautiful light bread without yeast. One trial will convince the most sceptical of its superiority over others.

[TESTIMONIAL.] "New North Road, London, N., May 4, 1875.

"Gentlemen, Your Baking Powder is decidedly the best I ever used, and I shall recommend it to all my friends, being positive that it is the VERY BEST.

"MARY WILSON, Matron."

Sold everywhere in 1d. Packets, 6d., 1s. 2s., and 5s. Tins, by Grocers, Oilmen, Chemists, &c.

Goodall's Custard Powder

For making delicious Custards, without eggs, in less time and at half the price. Delicious to plum pudding, delicious to jam tarts, delicious to stewed rice, delicious to all kinds of fruit, delicious to all kinds of puddings, delicious to all kinds of fruit pies, delicious to everything, delicious alone. Unequalled for the purposes intended. Will give the utmost satisfaction if the instructions given are implicitly followed. The Proprietors entertain the greatest confidence in the article, and can recommend it to housekeepers generally as a useful agent in the preparation of a good custard. GIVE IT A TRIAL.

Sold in boxes 6d. and 1s. each by Grocers, Chemists, Italian Warehousemen, &c.

[TESTIMONIAL.] "London, 5th February, 1879.

"Gentlemen,—Your Custard Powder is simply delightful, and cannot be approached by any powder I have hitherto used. "Yours respectfully, E. P

"To Messrs. Goodall, Backhouse, & Co., White Horse Street, Leeds."

Goodall's Ginger Beer Powder

Makes three gallons of the best Ginger Beer in the world for threepence. The most valuable preparation for the production of a delicious and invigorating beverage. This Powder stands unrivalled, possessing valuable medicinal properties to a very large extent. It is not only cooling in its nature, but also an invaluable stomachic, thereby rendering it the most wholesome and perfect beverage ever discovered for both winter and summer. It is easily made, and acknowledged to be by far the cheapest and best Ginger Beer Powder ever offered to the public.

CAUTION.—To prevent disappointment be sure and ask for GOODALL'S GINGER BEER POWDER, as most of the so-called powders are made up of inferior articles, and contain little or no Ginger. Sold in Packets, 3d. and 6d. each, by all Grocers, Chemists, and Italian Warehousemen, &c.

Goodall's Egg Powder

The most valuable preparation in the world. Universally acknowledged to be the only real substitute for eggs yet discovered. This truly wonderful Powder has not gained its high reputation without meriting it to the fullest extent; its action on Cakes, Puddings, &c., &c., resembles that of the egg in every particular, enriching them in colour and flavour; also rendering them most wholesome and nutritious. Those who have not given it a trial should do so at once; they will find that one penny packet will go as far as four eggs, and one sixpenny tin as far as twenty-eight, thus making the cost one-fourth that of eggs. Sold everywhere, in 1d. packets; 6d. and 1s. tins. By Grocers, Oilmen, Chemists, Italian Warehousemen, Ship Store Dealers, &c.

Sole Proprietors and Manufacturers, } ***Goodall, Backhouse & Co., White Horse St., Leeds, ENGLAND.***

9, ESPLANADE-ROW, CALCUTTA.

IMPORTERS OF

Machinery, Engineers' and Planters' Tools of all Kinds:

ALL ARTICLES SOLD AT OUR ESTABLISHMENT ARE MANUFACTURED BY FIRST-CLASS FIRMS, AND ARE OF THE BEST MATERIAL AND WORKMANSHIP.

Clayton & Shuttleworth's Portable Engines, 6, 8, 10, and 12 H.P.
Punching and Shearing Machines.
Improved Saw-sharpening Machines for Frame and Circular Saws.
Seller's Bolt and Nut Screwing Machines.
Drilling Machines with Feed Motion and Rising Table.
Bench Drills for Hand Power, 15", 20", 25".
Bench Drills for Hand or Steam Power, 42".
Slotting Machines.
Lathes—Self-acting, Slide, Screw-cutting, and Surfacing.
Foot Lathes.
Lathe Carriers.
Asbestos Packing.
Circular Saw Benches for 36" and 42" Saws, and with Patent Self-acting Drags.
Circular Saw Spindles.
Crab Winches, with and without break, to lift 4, 6, 8, and 10 tons.
Brick, Tile, and Pipe Machines.
Improved Brick Pressing Machines.
Screw Jacks—Bottle, Tripod, Haley's Patent, and Traversing.
Iron Pulley Blocks for Rope and Chain.
Weston's Patent Differential Pulley Blocks.
Blast Fan, Silent, for 16 and 30 Fires.
Sodawater Machines, to make 100 and 150 dozens a day.
Sodawater Bottling Machines.
Parallel Vices.
Tube Vices, with and without side Gate.
Boiler Bears.
Duplex Punches.
Indigo Press Screws with Brass Nuts.
Appold's Centrifugal Pumps.
Chain Pumps
"Special" Steam Pumps.
Steam and Horse Ploughs, Harrows, and Hoes.
Fire and Garden Engines.
Watering Carts.
Water Lifts.
Rice Shelling Machines.
Flour Mills for Hand Cattle, or Steam Power.
Flour Dressing Machines.
Chaff-cutting Machines.
Corn Crushers with fluted Rollers.
Prize Corn Crushers with Smooth Rollers for Crushing Oats, Linseed, Malt, Barley, Gram, and for Kibbling Beans, Maize, &c.
Cart and Portable Weighing Machines.
Domestic do. do. with and without weights.
Salter's Spring Balances.

A large Stock always on hand of Best Sheffield Files and Patent Woodscrews, Locks, Bolts, Hinges, Nails, Chain, Iron, Steel, Brass, Copper, Zinc, Tin, Lead, Oil, Paints, Varnishes, and Turpentine.

Prices and Particulars on Application.

until the light yellow has deepened into golden or light brown. When at this stage, all windows may be thrown open, and the plants may be hung close together on the highest tier; the evaporation from the leaf will be very little now. The drying and changing colour of the leaf generally begins from the margin to the mid-rib, when the mid-rib is entirely dried up and pliable, the tobacco is ready for the next process—"stripping." As before said, for stripping, the leaf must be perfectly soft and elastic (a damp moist vault would make a good stripping-room). In the early mornings when the plants have absorbed some moisture, they should be first heaped to check evaporation, and stripped when the leaf can be best rolled and bent without breaking. The leaves, when stripped from the stem are at once "sorted." There should be four sorts thus, No. 1, large equal coloured and untorn; No. 2 large equal coloured and torn; No. 3, bottom leaves of inferior colour, and No. 4, refuse and shrivelled up leaves. Nos. 1 and 2 are used for wrappers. The leaves are next carefully smoothed down on a flat board, and tied up in "hands" from ten to twenty leaves each, according to the size of the leaf. Should the colour of these "hands" not be uniform, to give them a brown colour they may be "bulked" that is to say heaped, so as to encourage a slight fermentation, but in this operation great care must be taken to avoid over-heating and mouldiness. If the tobacco has been carefully dried, and is of a good variety, it may be smoked a week after curing. Many ingredients are used in the trade for improving colour, flavour, &c., but it is wiser, we think, to leave all this to the cigar manufacturer. It should be remembered that a good cigar depends much more upon the rolling and wrapping than is generally supposed, and many a good quality cigar is thrown away in disgust, although the tobacco is of the finest and the leaf has been carefully tended and cured.—*Ceylon Times.*

TOBACCO IN MYSORE.

LOVERS of the fragrant weed—and they form a large body—must be interested in everything that relates to the better development of the tobacco plant. There has from time to time been a good deal of talk about making improvements in the growth and after preparation of the plant, but very little has been done to carry out the suggestions that have been made. Tobacco is grown in most parts of India, but very little is imported to Europe, and the reason of this is not far to seek. The production of this country is considered inferior to that of other parts of the world, and hence it finds but few purchasers in the home market. But it is very remarkable that with every kind of soil and climate the growers should not be able to produce an article equal, if not superior, to that grown in America and other places; skill and capital alone are required, we should fancy, to bring about a change in this respect, and we believe that a good deal of money might be picked up if any one would set about the business in the proper way. Why should not this province grow the plant to a greater extent than it does at present? There must be plenty of places where the soil is propitious, and probably there is not a better climate for its growth in any other part of Southern India. Before the famine, tobacco was cultivated in large quantities about the village of Bettadhapura in the Mysore district, but we believe the cultivation has fallen off a good deal during the last few years The soil is rich and well suited to this peculiar cultivation, and years ago this was taken advantage of by the ryots in the neighbourhood. But even in its palmiest days this district did not produce so much tobacco as it might have done, either from the pressure of taxation, or from the want of a suitable market. The plant found its way, it is true, to other parts of the province and perhaps beyond, but not in sufficiently large quantities, while in some cases the ryots only grow enough for their own wants. The late Mr. Broughton of Ootacamund examined the tobacco grown in the district, and pronounced it to be, in some respects, equal to that raised either in Manilla or the West Indies. Mr. Broughton analysed the tobacco in order to find out the amount of nicotine in it when dried, and the amount of potassic carbonate in the ash, and from the report that he gave, we find the following:—

Nicotine, per cent.	3·61
Ash, do.	15·35
Amount of potassic carbonate contained in the ash of the tobacco, per cent.	3·23

He discovered that the greatest fault in the tobacco was a deficiency of potash salt, and this he thought might be remedied by greater attention being paid to the cultivation of the plant. If this could be improved, the flavour of the tobacco would be better, and it might find a ready sale outside the province.

There must be many other parts of the province equally suitable to the growth of tobacco as the district we have mentioned, if only little trouble were taken to find them out. The plant is considered to be of hardy growth, though, of course the quality depends upon the kind of soil that the plant is placed in. Tobacco in order to be brought to perfection requires a good, red soil, such as is found in several parts of the Astagram district. The cultivation is not difficult; the land requires to be well manured before the planting takes place, and, only at the time of transplanting, irrigation is required; after that the plants may be left to the rains of heaven. The method of cultivation is known to every ryot, and need not be described here. There is plenty of land in the province waiting to be tilled, and tobacco, if good, finds a market all the world over, so that it is a pity that its cultivation should not be taken in hand on a large scale, and not be carried on with more care. There is, as we have said, money to be made, and it only requires a little capital and skill to make it.—*Bangalore Spectator.*

WITH THE NUMBER OF

THE INDIAN TEA GAZETTE,

OF WEDNESDAY, MAY 19th,

WAS COMMENCED A SERIAL STORY OF MUCH INTEREST AND INSTRUCTION

TO TEA PLANTERS.

ENTITLED

JACK RAYNSFORD—Planter,

A Story (Founded on Fact)

ILLUSTRATING

The Life, Experiences, and Adventures of a Tea Planter.

The Story is being continued throughout Volume VII., and is separately paged from the rest of the *Tea Gazette*, so as to permit of its being afterwards bound up by itself.

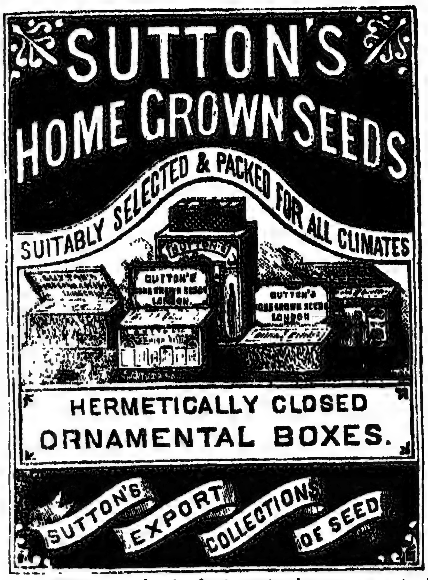
The Work has been written by a TEA PLANTER of great experience, and will be found to afford equal instruction with recreative reading. It deals, also, with the incidents and occasion of the late Naga Raid, and other Historical Record connected with Tea in India.

The Work is copyright, and can only be obtained by present or future Subscribers to the *Tea Gazette*.

Volume VII (No. 73 of the Series) of the *Tea Gazette* commenced with the No. of June the 2nd, but new Subscribers will receive the back issues of the Tale.

The Half-yearly advance Subscription to the Indian Tea Gazette is Rs. 9.

10, HARE-STREET, CALCUTTA.



May be obtained of duly authorized Agents in every part of the world, including—

Messrs. KING, HAMILTON & Co., Calcutta.

The Proprietor, "INDIAN AGRICULTURIST," Chowringhee-road, Calcutta.

NOTICES TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

CORRESPONDENCE.

CARDAMOMS.

TO THE EDITOR.

SIR,—Having seen an article on the cultivation of cardamoms in your paper of the 1st July, I shall feel obliged if you or any of your readers can inform me where I can procure a book on their cultivation.

August 1880. MALABAR.

NOTE.—We believe there is a work by Dr. Pereira on the subject of spices, which would probably give our correspondent all the information he requires. We have not seen the book ourselves, and cannot therefore speak positively.—ED., *I. A.*

SILK.

TO THE EDITOR.

SIR,—Can you inform me, through the columns of your paper, whether or not the Eria cocoon has a marketable value in Calcutta, and if it has, what is its value per maund?

Assam, 7th August 1880. W. S. YOUNG LESLIE.

NOTE.—The "Eria" like all the wild cocoons of India will always find a market in Calcutta. A reference to a silk broker will get you the present value.—ED., *I. A.*

INFORMATION WANTED.

TO THE EDITOR.

SIR,—If A.B. has succeeded in domesticating the silk-worm *Antheræa Paphia*, will he kindly send particulars and say if he has any eggs to spare? If any of your readers can give information regarding the winding off of the Eria cocoon, I shall feel extremely obliged. Can they be reeled in the same way as the mulberry feeders?

ONE INTERESTED IN SILK.

Ghatal, 28th August 1880.

PAPER FIBRES.

TO THE EDITOR.

SIR,—Having read in your paper several articles on the matter of obtaining cheap materials for manufacturing paper, I have the pleasure to inform you that I have posted this day to your address a packet which contains two samples of fibres, No. 1 taken from the Lady-finger plant, and No. 2 from branches of Jaintl. Both of these plants grow very rapidly, and without any particular care being paid, except to extract the fibres. No other materials could be obtained more cheap than this kind, provided it answer the purposes.

August 1880. B. L. FRIZONI.

NOTE.—We are obliged to our correspondent for the samples which came duly to hand: we shall be happy to show them to any one desirous of inspecting the same.—ED., *I. A.*

PRESENT STATE OF JAMAICA.

TO THE EDITOR.

SIR,—This island is a very fertile one, with rich woodlands and scanty sugarcane fields interspersed everywhere. Its rise depends much on the su[illegible]op, and, as that plantation has failed, the island looks gloomy, not because [illegible] cloud overhangs her, or because the sun does not shine, but because there is not much work, no demand for labour, and consequently the place has in three hundred and sixty-five days only ninety brisk ones. The land, notwithstanding the several fictions (that it will not yield after two or three years' plough) is highly fruitful, and to add to its fruitfulness, running streams, springs and ponds are to be met with wherever one turns, so that when much rain does not fall: there is very little of the cry "everything is scorched."

The disadvantage from which the island is now suffering is not merely from the want of labourers (as is the general rumour) but on account of planters not having sufficient capital to continue on the working of the cane fields. All the old planters have quitted the planting field, and those who have succeeded are inert on account of the prior reason—*viz.*, insufficiency of capital, there fore there is an end to general employment and occupation.

This island which once carried the name of the "great sugar country," is not so now ; other places have arisen and she has sunk several steps lower than the rest of the "sugar manufacturing world."

And now the question arises—When shall Jamaica again reach her former zenith ? The question may be fairly answered thus :—

1. When planters think again of cultivating those sugarcane fields which have grown with noxious weed and unwieldly wood.

2. When planters know again the value of the products of Jamaica.

3. And when they will plan not only to cultivate sugar and rum, but other products of commerce which will serve to be profitable to them, and of use to those demanding.

Of the many acres of land, not half can be said to be in thorough cultivation, and according to a late report, it is still decreasing on.

Many who have tried to relate of the advantages and disadvantages of this island, say that labourers are required. When this was said before, it conveyed a right meaning ; but we may now safely assert that the island is in need of men withstanding, capital, —persevering men, and men who have an adscititious brain than the common majority.

Another cause of this island's failure is party prejudice, but as this exists among the lower classes and the vulgar, who are uneducated, I will not then lay it as a general source of grievance.

Montego Bay, Jamaica, April 25, 1880. CRITIC.

DISEASES OF THE TEA PLANT.

TO THE EDITOR.

SIR,—We read, hear, and see a great deal about the different diseases to which the tea plant is more or less a victim in the various districts where this cultivation has been undertaken, but up to this time no writer has been found to show us clearly the means by which we may be able to keep our plants free from diseases, which in some instances prove fatal.

Some attribute the cause to bad soil, others to pruning, &c. ; doubtless the former being one of the chief causes, cannot be disputed. Nevertheless climate too, I dare say, has a share. For instance one may observe that plants on a tea estate at a high elevation are not so much attacked by bug as those lower down. The rapidity with which these little creatures increase in number is marvellous. From the time when first a bush is attacked, the number are so few, that one may almost count them, but note the difference two months later, and you will be surprised, most likely the whole plant is one mass. A little later you may find your plant is no more : it begins with shedding its leaves, and gradually the tree dies out.

Hints from the pen of some scientific man, I dare say, will be of great worth to some who have failed to hit upon means of getting rid of this pest. I have tried lime, tobacco-water, and other things which I thought would be disagreeable to the insect class, but all to no purpose.

A proof of soil being poor, may be somewhat arrived at by the appearance of plants put out on it, which will in the one case show vigour and the other, appear sickly and sluggish in growth, but this may easily be rectified by the attention of the planter being drawn to supplying what is necessary. Much is said regarding chemical or artificial manure, but very few will dispute that ordinary earth manure is as good as any, and, if applied proportionally, will produce the desired results.

I wish here to say a word regarding a disease (I can call it nothing else) which may yet be a stranger in some districts, and as "prevention is better than cure," [illegible] very far some may, through hints fr[illegible] the scientific writer, be able to check the evil while yet in the bud.

The estate where I first observed, what I am about to point out, is barely four years old.

The soil though not of the very best kind, is to all appearance one that could nourish tea plants for the next twelve years to come without application of manure of any description. I observed till May last the plants looked quite healthy. Since then several have as though commenced to fall back, and a great number seem dying. These appear to commence dying at the branches, beginning at the upper end, till they reach the main stem, and gradually the tree perishes. The space of time I calculate from the first signs of dying to the complete dying out of a plant does not exceed three months. On digging up one of the bushes which perished in this manner, I observed that the roots were slightly covered with a white substance, much like fungus in appearance, or as may be seen on trunks of decayed trees.

It would be a great favour conferred if any of the contributors to your valuable journal would be good enough to give us an insight as to cause and remedy, by which we may be saved a further loss of our tea plants by this disease which is quite a new thing to me, though to men of long experience it may be quite familiar. We can but look to men of sound practical experience to help and enlighten the ignorant and

Neilgherries, 21st July 1880. "IGNORAMUS."

THE FOOD OF CATTLE.

TO THE EDITOR.

SIR,—With respect to several letters that have appeared in the *Agriculturist* on the subject of feeding cattle, I would offer a few remarks, leaving it to those interested to think and act for themselves. In the matter of feeding cattle with either raw or boiled grain, I have seen horned cattle fed with raw gram, a bean called "Moochacotay" in Tamil, in Bengal called "samo." This when well soaked, they pounded into a thick pulp in a mortar and gave to the cattle. In this way the cattle must derive more benefit than by simply soaking and giving the grain entire, because, as one of the writers has acknowledged, the grain is sometimes passed out entire. This method of giving the grain in pulp can only remove one objection, *i.e.*, there can be no loss of food from indigestion. But who that has seen grain in its various conditions, will be satisfied with that ? If the grain is simply to be soaked, then what becomes of all the worms, and such like, as well as their eggs which both horses and bullocks have to swallow, breed, and in some instances develop into other stages of existence, and which meantime go on drawing all the nourishment required for their existence at the expense of the health as well as the life of the animal they are breeding in and living on ? If boiling is really objectionable, then *broil* well ; the gram may then be given in that state or soaked. By this means, about one-half, or less, fuel will be required, and all vermin will be destroyed, the grain meantime becoming more palatable and easier of digestion. Your Seringapatam correspondent's letter contains these words :—"But it is the belief amongst the native that this would produce colic, inflammation of the bowels," &c. I will just give one instance from my own observation to prove the soundness of the native views. During the late famine in Madras, as horse gram (*coolty*) had become very scarce, residents in those parts bought the Bengal gram (*chenna*), soaked it and gave it to their horses. A friend complained that "not only were people of all classes suffering in various ways, but horses too ; and I was assured that both the horses of the house in question had been totally unfit for work for some time, as shortly after their feed their belly would swell, and they would lie and roll and groan as if in great pain. I learned during the day that these horses had the Bengal gram *soaked* and given them, and I at once advised the boiling of the gram, when to the astonishment of all, the horses became perfectly well, and fit for work : there was *no more soaked gram.* The cause in this case no doubt lay in the germ which heat neutralized. Not a particle of the strength of boiled gram need be lost to cattle. Cool the water that is strained from the boiling, and give it to the horse to drink. If the horse won't drink it that way, pour it into a tub to ferment, then with the addition of his usual allowance of water give it to him. He will certainly drink with a relish in its sub-acid state. To this add the water that rice is washed with in the first instance, before boiling, as well as the water strained from the rice after it is boiled—this in hot weather will be drunk with great relish by all cattle. In the days of yore, say sixty years ago, ship captains in Madras paid *one double fanam* (2½ of an anna) for the full of a quart-pot, a couple of green chillies being cut up in it as a zest. But there is another item of diet for the horse that must not be lost sight of, *viz.*, grass. How is this got ? A woman or man digs it up, roots and all, with a kind of hoe, consequently it has to be washed, to free it from the clay, &c. During the rains there may be plenty of clean water handy, but in the dry season water is not only scarce, but what little there may be is often in the filthiest condition, and quite alive with animalcule, &c. Into these sinks the grass is thrown to get rid of the earth, and there it is often allowed to lie, to enable it to get a fresh appearance. Is it not likely that in those stinking cesspools the grass gets filled with animalcule, worms, &c., and is it not from this that the horse gets all the ringworm, sores, and itch he may be attacked with ? Let your readers think on this and insist on grass being brought to them without being washed outside in the fields or villages ; let it be washed at the house or stable with well water. I recollect seeing a buffaloe killed as an offering to "Mariatha" during cholera time ; the stomach was full of the grass it had eaten, and in it thang

was an immense amount of small leeches, which were all of a pale pink colour and alive. If the animal had the power of digesting these, well and good, but if *they* had the power of adhering to its intestines, then what wonder at the great mortality that often carries our cattle off by scores, while all directly interested, wonder why, and never know.

Now if it is a fact that gram becomes "heaty" if boiled, the remedy is within the easy reach of all. To a measure of wheat or fine rice bran, add one desert spoon of nitre (saltpetre), finely powdered, and about a tumbler of treacle that has been well boiled, give this once a week during the hot season, to your horse; it will cool his blood: I know this to be given, and with good result.

Give your horse, occasionally, some ripe plantains of the large coarse kind, slices of ripe pumpkin and water-melon, all of which are cheap and plentiful in most parts of India.

Take a real interest in your cattle, look at all that is given to them, see that all is clean and wholesome, and put a proper quantity of salt in their food. Sometimes give good, clean treacle; let this be well boiled and kept corked in bottles; it will do more good than the bare insipid gram and other grain, without the least particle of anything to make it palatable.

The health of our cattle depends often on the care bestowed on them, let us do our duty to them, as they minister not only to our wants, but to our comfort: and let us always bear in mind that the righteous man is merciful to his beast.

Those who give cotton-seed to milch cows, should make sure that the seed is fresh and sweet; old and rancid seed is only fit for manure.

12th August 1880. OBSERVER.

TEOSINTE A MEXICAN FODDER GRASS.

(*To the Editor of the Ceylon Times.*)

SIR,—I am surprised that no one has recorded their experience of the Teosinte fodder grass. The prickly comfrey was decidedly a failure —not to say a swindle. Of course it is a fodder for cattle and so are turnips and cabbages. It can be made to grow luxuriantly by garden cultivation, but it "won't pay." The Mexican grass is certainly a paying thing to grow, for while in guinea grass the thick stalks are unpalatable to cattle, the Teosinte has an advantage, *viz.*, that the thick stalks no matter how thick, are devoured by horses, cattle, and pigs, owing to the saccharine matter they contain, the manure would not only be superior, but the beasts themselves must fatten. There are certain places where Guinea or any grass won't grow. It is not expected that Teosinte can flourish on such soils. As a rule instead of a bad piece of ground being turned into a grass field, I would advise a small portion of really good ground to be selected for any kind of fodder grass. A little trouble in loosen ing the soil occasionally and replanting after breaking up the old clumps and clods, a little expenditure on artificial manure to be applied at the rate of 10 per acre including labour, will go far to give an immense quantity of substantial fodder making rich manure. The proportion in weight is as nearly three of Teosinte to one of Guinea grass, judging from the result obtained from a small plot of each grass treated equally. The quantity remaining in stalls of Guinea grass after feeding cattle when weighed, shewed 27 per cent. unconsumed, of the Teosinte only 11 per cent. To those who take an interest in a fair number of cattle and look to improvement in the stock, and to a good supply of rich manure, with but a small porportion of troublesome long stalks to impede the turning over and heaping or removing the manure. I strongly advise the planting of the Teosinte. It grows well on banks of roads and drains, and luxuriates in ravines. Its habit is not unlike the Indian corn these are the male and female flowers. The grass should not as a rule be allowed to run to seed. The rapidity with which it grows after each cropping is simply extraordinary, and from a single stool raised from one seed, as many as 17 perfect stems have been got by mere cropping. Length of average blade is 3 feet 9 inches, but many a foot more; general width in centre 2 to 2½ inches. Mind I speak of grass well attended to. I had read and heard of the grass, but never cared to experiment until in Galle a ship captain who had been to Mexico and knew the grass, confirmed the accounts given of it. He spoke also of two other good prarie grasses which he thought would suit the low-country marshes.

L. T.

FORESTS AND RAINFALL.

(*To the Editor of the Bombay Gazette.*)

SIR,—Anent the subject of forests and rainfall, I would remark that the pretentions of forest conservators remind me of nothing more vividly than the claims of the African priest and medicine man. To quote a popular work:—

"The African priest and the medicine man is one and the same, and his chief function is to make the clouds give out rain. The prepartions for this purpose are various—charcoal made of burned bats; internal parts of animals, as lion's hearts and hairy calculi from the bowels of old cows; serpents' skins, and vertebræ, and every kind of tuber, bulb, root, and plant to be found in the country;" in short, all "forest produce." Although you disbelieve their efficacy in charming the clouds to pour out their refreshing treasures yet, conscious that civility is useful everywhere, you kindly state that you think they are mistaken as to their power; the rain doctor selects a particular bulbous root, pounds it, and administers a cold infusion to a sheep, which in five minutes afterwards expires in convulsions. Part of the same bulb is converted into smoke, and ascends towards the sky; rain falls in a day or two! The inference is obvious!"

So also is it with the forests and rainfall! The thing is quite plain. The rain tree must induce rain, and the Jovian functions of forests conservators and their assistants are beyond all proof and question. Some things are above reason?

July 23.

JUPITER PLUVIUS.

THE COFFEE BORER.

(*To the Editor South of India Observer.*)

SIR,—In your issue of the 31st July, there is a local para. referring to the ravages of the "borer" in the Nellacotta to the district. It has been very generally remarked here, by all who have seen the para. in question that it is calculated to convey the impression that some of the estates in the district are suffering from exceptionally severe attacks of this insect. This is by no means the case. The facts are rather that there is less "borer" this season, on the whole, than there has been for years past. Every season we have borer, more or less, but during my six years' experience in the district, I have never known any estate to have suffered from an expectionally severe attack. As is the rule in the Ouchterlony Valley, so here, the trees attacked are regularly and systematically cut down and burnt at this season of the year. If the insect does make an invidious distinction in the trees it selects to attack, I should certainly say from my experience that weak and indifferent trees very generally appear to bear the honor of the distinction, and not so much the best trees, as stated in your para.

NELLACOTTA PLANTER.

Nellacotta, August 4, 1880.

A NEW VEGETABLE.

(*To the Editor of the Ceylon Times.*)

SIR,—As you are paying a good deal of attention to new products, perhaps you will allow me to call your attention to the following account of what is termed in home papers "a new vegetable," and to ask if it has been grown in this island. It is the *Soja hispida*, a species of leguminous plant, somewhat resembling in habit and appearance the well-known pea. Unlike the latter, however, it has two distinct uses—industrial as well as alimentary. It is highly prized in China and Japan, and is said, indeed, to take its scientific title from the Japanese name of a sauce-sooja—which is made from its seeds. The seeds are very similar to a "marrow-fat" pea, but contain a large quantity of oil, which is either pressed out of them or boiled out in process of cooking the seeds for the table which is effected by simply throwing them into boiling water, when the outer skin bursts and floats to the surface, together with a quantity of oil, both the oil and the husks being skimmed off together. These may be either used as cattle food, or the oil may be separated and employed for various purposes, while the husks are still valuable as a feeding stuff or as a manure. The peas are boiled for about twenty minutes, and furnish a dish which is highly relished, not only by the Celestials, but by many Europeans who have tasted it. It is said to resemble in flavour the green pea, but lacks its sweet taste. The boiled sofa is also prepared as a cake and as a sauce, being fermented for the latter purpose, and salt, pepper, &c, being added. The sauce has a high reputation among the Chinese and Japanese, not only as a condiment, but as a medical agent.

The plant is described as thriving in very poor thin soil, and as adapting itself to a variety of climates. In Ceylon we are most deficient in the matter of vegetables for culinary purposes, and this would, from the account given of it, appear to be well suited for us and easily grown.

July 16. B. B. D.

THE WILD VINE OF CALIFORNIA.

(*To the Editor of the Englishman.*)

SIR,—I have just brought from San Francisco a small parcel of seeds of the wild vine of California (*Vitis Californica*), which I shall gladly distribute to persons desirous of having them, and who may be able to put them out in suitable localities.

The California vine is now very much valued in Europe, and if these seeds should be successfully grown in India, they might be the initiation of an important and valuable industry, either for making wines or raisins.

Will you please make this known in your paper and oblige—

JOHN MARTIN.

5, Garstin's-place, August 14, 1880.

WHITE ANTS.

(To the Editor of the Times of India.)

SIR,—Your Ahmedabad correspondent "Hortus" calls for a cure for a disease which does not exist. It has been proved scientifically that white ants will not eat any vegetable with vitality. I would, therefore, suggest that HORTUS should look to his *malee's* method of planting or weeding, for I find if a rose-tree gets a knock with a *khurpee* or other tool injuring the bark, it admits water and causes death, when the white ants immediately seize it, the top remaining fresh and green for some days. Probably the *malee* detects, or you yourself notice, that the tree is looking sickly, and the roots are then examined for the first time, but the white ants may have found it out long before.

Baroda, August 8. GUZERAT.

The Indian Agriculturist.

CALCUTTA, SEPTEMBER 1, 1880.

THE BENGAL RENT LAW COMMISSION.

WE expected a good deal from the Commission appointed to draft a revised rent law. The experience of Mr. Dampier, the industry and legal lore of Mr. Field, the talent of Mr. Mackenzie, and the critical acumen of Mr. Harrison, with Mr. O'Kinealy's zeal for the improvement of the condition of the cultivators, could scarcely have failed to produce much when applied to a subject so important as the reform of our land system. And the report which the Commission has sent in fully justifies the hopes which had been entertained. Taken as a piece of literary and legislative work it is the best of its kind, as far as our experience of such productions in India extends. The Digest, which is its basis, gives a complete statement of the law as it stands, incorporating all changes, additions, and explanations by which the decisions of the High Court have supplemented the regulations and laws passed in Council. Sir Richard Garth has pronounced this work excellent, so that there is the best authority for assuming that the labours of the Commission rested on the only solid foundation,—a thorough knowledge of the laws which it is desirable to amend. The draft Bill now submitted goes over the whole ground to be covered; it is clear, logical, and exhaustive. The report by which it is prefaced gives in forcible language the reason for every change which it is proposed to make. We may say that the light of day has for the first time been let in upon the subject, that it has been treated in such a manner that any statesman or student, whether in another province or in England, can master it without the aid of local knowledge. On the question itself it is vain to look for any general agreement; in India, as in every other country, there is a landlord's party and a tenant's party, and the two can never agree when the measure under discussion is really important; but we believe that all will be glad to acknowledge the utility of a work which ensures that the legislature, in whatever direction it moves, will have the guidance of light and reason.

The Commission has made several proposals most favourable to tenant-right, and which certainly should meet with our approval, as we have long advoc[illegible] them. It is a defect in the present law that, [illegible] careful of the rights of privileged ryots, it has no provisions whatever for the protection of the ordinary tenants who form a moiety of the whole, and are becoming a majority. The landlord may rack-rent them or eject them at pleasure, or may appropriate without payment such improvements as they have made, such as the trees planted and reared, the wells sunk, the enclosures formed. It has even been decided in a recent case that a landlord thus evicting may take the standing crop, however valuable, and however near maturity. With regard to these unprivileged ryots, the Commissioners have remembered that, as a Trinity man at Cambridge is said to have charitably remarked of the undergraduates of the smaller colleges, "these, too, are our fellow-creatures." Ryots who have been in possession for three years are declared to be entitled, on ejectment for some cause other than an arrear of rent, to compensation for improvements effected by them. They can also get one year's rent as compensation for disturbance. In Ireland, from which the phrase and the thing is borrowed, compensation for disturbance may amount to five years' rent, so that it appears that the Commissioners can move in the direction of tenant-right only at one-fifth the pace of Mr. Gladstone's mighty strides. The compensation for improvements, too, is not assigned as freely as in the Act of 1870. Moreover, it is not clear why a tenant so unfortunate as to be ejected before he has been three years in possession, is to get no compensation for the improvements from which he cannot have as yet derived benefit. It would have been better had the proposal of Mr. Mackenzie, supported by Mr. O'Kinealy and Baboo Rajendro Kumar Seal, been adopted, and the three years' ryots raised at once to the privileged class, in which case their proposed status might have been inherited by the residuum, the unfortunate tenants left unprotected because they have not held for three years. But we must say that, voting in January, before the recent change of Government, the Commissioners went as far as could, at that time, have been expected. It is of little use to propose measures which, with reference to the known views of those who from above control our policy, are sure to be rejected. The Commissioners did as much for the ryot as was possible at the time; when Sir Ashley Eden meets his Legislature next season, he will be in a position to go much further, and really to settle the question.

On the occupancy or privileged ryots it is proposed to bestow this further right, that their holdings shall be alienable. At present such holdings may be sold or not according to custom, and it is always difficult to find out what the custom is in a particular place. There are some who believe that if ryots are given the right to sell, they will dispose of at once their tenures to the money-lenders; but this view, though plausible, is not borne out by experience. At present there are at least a hundred thousand alienable tenures in Bengal, from those of the peasant taluqdars of Chittagong on the south-eastern frontier, to the Surbarahars and privileged ryots of Orissa on the south, and the Gurjashtadars of Shahabad on the west. These are bought by money-lenders only occasionally, and the class connected with them shows no tendency to die out. The idea of declaring all occupancy right saleable is, as far as we know, Sir Ashley Eden's own, and it strikes us as being what *Punch* calls a happy thought. Nothing gives the proprietory feeling but the power to sell, and it is to the pride of proprietorship that we must look to to urge the ryot to improve. In fact it may be said, as a general rule, that all ryots with alienable tenures are now well off, and no others, except where population is thin. If the bulk of the ryots are given this privilege, there is room for a reasonable hope that they may become prosperous.

Since Sir Ashley Eden took the reins we have heard less of the wild schemes for unlimited enhancement of rent on new principles, which Sir Richard Temple declared that he would have invented. Baboo Kristo Das Pal heads a party which openly aims at depriving the occupancy ryots as a body of the statutory privileges they at present enjoy as to fixed rent rates, giving them in exchange other privileges of less value. He nearly succeeded in carrying out his purpose in Sir Richard Temple's time, procuring the introduction of a Bill which, if passed, and maintained, would have led first to an agrarian insurrection, and then to the general impoverishment of the cultivators. We are glad to see that the Commissioners have given no encouragement to these wild and pernicious views, and that even the native members who represented the landlords' interests, did not put them forward. The occupancy ryots under the draft Bill retain their right to hold at the old rates, subject to enhancement only on the old grounds. They are further protected against rack-renting by some new precautions. Enhancement can take place only once in ten

years, and in certain cases it cannot be carried to so great an extent that the rent shall be more than doubled, and in no case shall the new rate be more than equal to the value of one-fourth of the staple crop. It may, moreover, be made by instalments.

The equivalent given to zemindars for the curtailment of their powers involved in the extension of tenant right, is the power to put in motion the revenue machinery of Government for the purpose of raising rent rates, as far as the law permits that they should be raised. The landlords complain that they cannot enhance their rents through the Civil Courts, the process being too clumsy and expensive. They are to be given the use of the agency with which Government effects its own settlements, and which may be supposed to be the most suitable which experience can suggest. This is undoubtedly a great boon to the landlords, and a great injury to the tenants. We, however, doubt whether it will please the shrieking brotherhoods of the Associations, which have got up the agitation for new means of enhancement. These are formed by the more powerful, active, and pushing landlords, who have already enhanced by what they are pleased to call the consent of their ryots to rates beyond those to which they are entitled under the substantive law, and no change which merely gives increased facilities for enforcing existing powers will be of any use to them. What they want is either that the ryots shall be deprived of their present substantive rights, as by Sir Richard Temple's Bill, or that their own hands may be strengthened for the purpose of extorting further "voluntary" enhancements, as by the late Bill, to enable Judges to refuse to hear witnesses for the defence in rent cases. The concession now given will be of use only to the quiet and moderate landlords, who remain in the background, and have no influence in the press or at public meetings, the organs of public opinion.

We may, therefore, expect, indeed we have already witnessed, a strong opposition to the Bill from the party headed by Baboo Kristo Das Pal, the only native influence which is a real power in the country. Sir Ashley Eden's personal connection with many of the leaders of this combination may do something to soften their hostility, but, as we apprehend, not much, their disappointment at the result of the agitation which, since the movement of the ryots of Pubna in 1874 to maintain and assert their position under the present law, has been carried on to change that law to the detriment of the ryots, will be too great. And the question arises, if the opposition of the zemindars must be encountered in any case, why make concessions to it which will not satisfy or mitigate it? If we are to have a tenant right measure, why not make it effectual, and therefore final? Why not dispose of the matter once and for all, as Stein did in Germany? The draft Bill, excellent as it is when compared with other measures recently introduced in the Indian and Bengal Legislative Councils, stops far short of this. For instance, it permits the landlord to contract himself out of all his obligations under the Bill. Now tenant right can never be permanently defended where such a breach for attack is left as this. It is the rift within the lute that maketh all the music mute. The Conservatives knew this, when, in passing a law to give compensation for improvements in England, without intending that the right to receive such should be effectual, they provided that the rule should not over-ride any contract. Mr. Gladstone knew it when, in 1870, he enacted that any contract between Irish landlords and tenants, purporting to exempt the former from obligations under the Act should be null and void. Under the Bill of the Commissioners, a zemindar may keep all his ryots tenants-at-will at rack-rent rates, if he only takes sufficient trouble. He can do this either by registered agreements, or by making them change their fields every three years, on the system which Sir Richard Garth states has been adopted for that purpose by landholders in the Central Provinces. The principle in Bengal should be that, as the revenue is moderate, so should the rent be also; and this rule should be made so strong and close, that the most powerful landlord should be unable to break through it or the most cunning to creep under it. If we do not adopt such a policy, Bengal must in the end be ruined by rack-renting, like Behar and Oudh. It would have been useless to have asked for a law of this kind a year ago, but now the hour has come, and we hope that Sir Ashley Eden will prove to be the man.

IRRIGATION IN SINDH.

IRRIGATION in Sindh is a subject of more than ordinary interest, as being attended by unique conditions. Elsewhere (except in some parts of the Punjab) irrigation is more or less of a luxury; in Sindh it is a necessity. The extension of civilisation in that region is commensurate with the water spread of the canals. These, of course, are all fed from the Indus; and indeed that river might claim honours not inferior to those of the Nile, if practical benefit were the test, apart from historical and traditional glories. Like the Nile, the river of Sindh flows through a rainless country, and swells mysteriously when the drought is greatest. Its floods are more widely used than those of Egypt; the cultivator does not merely scatter his seed as the waters retire, but tills fields far removed from the river by the help of long canals. The system of Indus Canals counts up no less than 5,643 miles, and waters more than two million acres, or about 3,200 square miles. To this area must be added the aggregate area of the tracts directly submerged by the annual floods; it is not shewn in the canal returns, but may be assumed at about half as much again, making a total of some 5,000 square miles redeemed from the desert by the bounty of the river. Sometimes the river fails in its ministrations: more frequently it overdoes them, sending down a volume of water that sweeps away embankments and bursts the canals. Such was the case in 1878-79, when the Kusmore embankment above Shikarpore was breached, and the floods joining their waters with those hastily contributed by the hill streams from the west, the gift of a sudden shower, swept over the whole country from Kusmore down to Sehwan. Repaired and strengthened, the Kusmore dam stood against the inundation of 1879-80; but a few weeks ago, it was breached again. These floods do great damage to the autumn crops, which are destroyed by submersion; but some compensation is got in the spring, when wheat and oil-seeds can be sown over a larger area than usual. Wheat, indeed, depends almost wholly on direct flooding, as distinguished from canal irrigation. The latter suffices to water the autumn crops while the canals are full, but when the river shrinks into its normal dimensions, the canals run dry, and there is usually no water left for cultivation in the spring. Exceptions are found in some favoured places, where the canal supply, besides irrigating the autumn fields, yields a surplus which can be stored in reservoirs or water-holes for use several months later, so that a crop of wheat can succeed one of rice or millet. Generally, however, canal-watered lands produce only autumn crops, and lands watered by floods give only the products of the cold months—wheat, oil-seeds, and pulses for the most part. Great uncertainty attends cultivation of this kind. If the floods come in short measure, the area sown is deficient; if they are excessive, it is an advantage to have a large area for sowing, on the condition that it can be sown in time; but often the waters refuse to recede till the season is past. The ideal floods, so far as wheat cultivation is concerned, would be those which should submerge the greatest possible area, and recede with the greatest possible rapidity. The character and extent of the inundation vary greatly from year to year; but on the whole years of flood are commoner and less harmful than years of drought. The year 1878-79 produced the highest inundation, yet recorded, and as a consequence, floods of a magnitude unknown since 1826; nevertheless, irrigation prospered, and the official report on Sindh Canals has little to chronicle but success.

Capital accounts are not kept up for all the canals, but the returns given show that a capital expenditure of 84¾ lakhs on certain lines brought in a net return of 2,40,000 rupees; that is to say, about 3 per cent. This return, however, ought to have been about 5 per cent., had revenue been fully levied from the canals in the frontier districts and Khelat territory. These are two works bearing the ominous names of the Desert and the Forced Labour (Begari) canal; and the assessing dues on the lands they water seem to be the same

as those which prevailed generally throughout Sindh until recent years, but never worked satisfactorily. The desert landholder is assessed to water at 10 annas 8 pie per acre, on the entire area of his holding; and he is supposed to cultivate one-third of this area annually, so as to effect a proper rotation of fallows; thus the rate per acre of cultivation would be two rupees. What he actually does, is to water the entire holding whenever he can get water enough, and then to cultivate it all, whether with autumn crops, or, if the water lasts, with wheat and other spring grains. In this way he gets off with one-third of the proper assessment per cultivated acre. Of course he loses his chance of fallowing the land, but that gives him little concern, for waste land is plenty, and he has only to throw up his whole holding when the year is out, and take up another of equal size. In Sindh Proper, this plan of cheating the revenue has been stopped by requiring the landholder to pay at full rates for the whole of his holding, whether cultivated or not; while the areas of holdings are at the same time restricted to what can fairly be brought under the plough in an average season, and fallowing is provided for by allowing the holder to relinquish fields successively, retaining a lien on them for two years after relinquishment. Some such arrangement will probably be introduced into the frontier districts sooner or later. Meanwhile, if the revenue returns for 1878-79 be examined, the productions of irrigation in Sindh will be found such as to satisfy the most exacting critic. The expenditure on maintenance and collection was 16½ lakhs; the revenue realised on account of canals was 29½ lakhs. But in truth, from the revenue officer's point of view, the virtue of the canals is inestimable; for without them there would be no revenue from these lands at all. The whole area of Sindh is about 34,000 square miles, only 13,000 of which are recorded as culturable, and about one-fourth of this latter area is, as we have seen, under canals. These figures convey a graphic idea of the desert and sterile character of the region; yet the lands recorded as unculturable owe their unenviable distinction simply to the fact that they lie above the level of the canals; and it may be found possible, in the long course of years, as the canals extend and trees are planted, to bring even these high levels under cultivation, by attracting rainfall as a consequence of afforestation. At present along a single canal (that of Forced Labour) the Canal Department can point to nine thousand trees planted by the waterside, eight thousand of which are *babul*, a tree very suitable to a country which has been called Little Arabia, for the *babul* is the very acacia which in the greater Arabia waves her yellow hair

> Lonely and sweet: nor loved the less
> For flow, ring in the wilderness.

But the yellow hair of the Indian *babul* waves unnoticed, save haply by some solitary Englishman riding home through the thorny jungle in a golden afternoon of March, when the air is heavy with faint perfume.

Sindh is in several respects one of the most remarkable provinces of India, and not least so with regard to irrigation. Nowhere else do we find an entire province dependent upon a periodical water-supply, and nowhere else are canals so emphatically productive works. The annual Canal Report for Sindh furnishes the most striking testimony to the benefits of a strong and upright Government, however far removed, by alien blood and creed, from sympathy with the people, under its rule. Native governors designed some of the most important works, but it is only British supremacy that can guarantee their continuance. Persia, Mesopotamia, parts of Arabia can offer examples of the fate of embankments and canals under the vicissitudes of Oriental despotism. A great monarch accomplishes a gigantic work; and his successors allow it to go to ruin; while the people, disheartened and pillaged, have neither the energy nor the means to do the repairs themselves. Even in Sindh, the annual clearances, so necessary to the efficiency of the canals, are not managed without some trouble. An inundation canal differs from a permanent canal in the circumstance that it receives flood water only, which cannot be turned on and shut off at pleasure. Stones and silt come down with the flood; the volume of water cannot be regulated at discretion, and often breaks away from control altogether, striking out new channels and leaving the old one almost undistinguishable. Another tendency of flood irrigation is to convert the canal into a river, and thereby destroy its utility as a channel for the economical distribution of water. Even in the best years, the work of clearance is no light one, and but for the steady pressure of the canal officers, it would be very imperfectly done. Here it is that the regularity and persistence of a civilised administration prove so useful. Much depends, too, upon the careful collation of statistics, shewing how irrigation stands from year to year. Greater accuracy in these returns of areas is expected as the revised land-revenue settlements are gradually introduced. At present, the estimates of irrigated area are to a certain extent approximate. In the settled taluqas, the data of calculation are the known areas of the 'survey fields' into which the land has been divided for settlement purposes. These fields, however, are often very large (some of them, in the earlier settlements, were as large as 60 acres), and the whole of a field may not be watered; so that in fact the irrigated area has to be estimated by a rough comparison between the known area of the field and the apparent proportion borne to that area by the portion irrigated. In the unsettled taluqas, which are found chiefly in the Hyderabad district, where irrigation is by the Persian wheel, the area is calculated by allowing an average number of acres to each wheel actually in work; while the area of flow irrigation is roughly measured each year. With the revised settlements, more manageable 'survey fields' will come into use, and the cases will be rare where any part of a field has to be left unwatered; thus the area of irrigation will be known with much more precision than at present. There is every reason to believe that it will go on steadily increasing. Sindh is a province which has a future before it. The opening of the Suez Canal has invested the Sindh canals with a new importance; and the wheat growers of Kurrachee now enjoy the advantage of greater proximity to the European market than their rivals in the broad valley of the Ganges or the rich uplands of Chuttisgarh. Nor is Kurrachee alone in this favoured position. Thanks to the railway, which now traverses the length of the province, the remotest taluqas of Shikarpore are but little behind-hand; and Sindh officers may well be excused for the peculiar pride with which they profess their belief in the development of a province which has been redeemed from the desert not less laboriously than Holland from the sea.

UNANIMITY AMONGST TEA PLANTERS.

THE recent meeting of planters in Cachar has illustrated an important phase in connection with the tea industry, and that is—the utter want of unanimity that exists among the planters, as to their wants from a legislative point of view. We remember—several years ago, the Government asked the tea interest to meet and help in compiling such regulations as should be calculated to give the greatest satisfaction in working, and an influential commission of officials was deputed to meet with these delegates. What was the result, why nothing, no two of them agreed on any point, and the only conclusion the Government could possibly arrive at was, that it would be time enough to redress grievances when the aggrieved should decide on what constituted their grievances. For years the friends of the planters have urged union among them, but it has all been in vain. Petty jealousies and local interests have interfered; for it is absurd to say that indifference is the cause, the planter is sufficiently active in airing his own personal grievances. The real cause is that what suits one planter, does not perhaps suit another, and, as each clings pertinaciously to his own idea of what is wanted in the way of legislation, nothing can be done. It is absurd to blame the local Government, which doubtless would so legislate that all parties would be satisfied, if that were possibility. But as there seems no chance of unanimity, what can the Government do? The new society at home, the *Indian Tea Districts Association*, has petitioned the Government for sundry alterations in the existing law, reforms the memorial calls them, and among these that urgently wanted improvement, the propriety of substituting a five years' agreement for the present three years' engagement, occupies a prominent place. Recently a meeting was held in the sudder station of Cachar for the purpose of emphasis

ing this memorial, with the result of as usual agreeing to nothing. The motion for supporting the movement for a five years' engagement as against one for three, was lost, and that by the casting vote of the Chairman.

This must tend materially to weaken the hands of the Association at home, and make them ridiculous in the eyes of the Government. Here they have been most earnestly urging a reform for the planters, which a large section of those planters have just declared they do not want. If the tea industry is to be relieved from oppressive legislation, the first step towards this enfranchisement will be the formulating of the objections to the present Act (VII. of 1873, B.C.,) and submitting a list of such amendments as are calculated to put matters on a fair and just footing. There is no one who knows anything of the tendency and working of that Act, but knows that it bears with undue severity on the planter; we shall simply indicate one or two points in proof of this. In the early days of tea-planting in India, when coolies were imported from their homes and set down in the midst of dense jungles, there existed room for such a regulation as that regarding the maximum price of rice, which was often only obtainable at famine rates. Gardens were frequently situated in isolated spots, far away from bazaars or centres of supply, and were often separated from these centres by long stretches of almost impassable roads, not unfrequently by immense distances without any trace of a road at all. Under these circumstances it was but fair to throw the onus of providing food for these ignorant strangers on the planter, and the fixing of a maximum rate, although not exactly in accord with the principles of free trade, was unavoidable. Now, however, everything is changed, the coolie can always command a supply of grain at ordinary bazaar rates, and if it be considered necessary to keep to the rule of making the planter supply rice at a fixed maximum rate, it would only be fair to make that rate fixed, whatever the price of rice. As matters stand at present, whenever rice goes above the maximum price, the coolie demands his thirty seers per month at the Government fixed price, but should prices fall below that limit, the coolie goes to the bazaar and buys in open market. This we hold to be unfair in principle. The planter loses heavily on rice, and he should be allowed the opportunity of squaring his account, when the price of rice is in his favour. If it be considered advisable to adhere to this idea, it should be so modified that the coolie should be bound to purchase from his employer all the year round at the maximum rate. A much fairer plan would be to assess the average loss to the coolie on this article of consumption, and add that, in monthly increments, to his wages, leaving him all the year round to make his own arrangements as to purchasing. The bazaar is usually close at hand, and there is now no difficulty in procuring supplies within easy distance of each factory. For his own benefit the planter might be depended on to see that the local bazaar was sufficiently close to be convenient to his labourers. This has long been a steady grievance, and one upon whose merits no difference of opinion exists. Another hardship is the ease with which a coolie can break his agreement; although the planter feels this sore to be a severe and costly one, his sense of fair play impels him to do justice to the labourer. He knows for instance, that the coolie may have cost him one hundred rupees to land on the garden, but he also knows that this sum did not go to the coolie's pocket. The whole system of recruiting wants remodelling, but it might perhaps be the quietest plan were the planter to allow this grievance to right itself, which it is doing steadily and surely by the help of improved communication between the recruiting districts and the gardens. The planter must, however, lay it to heart—and this brings us back to the subject we started with—that no satisfactory redress of this grievance or of any other, will ever be attainable until a network of associations is spread over the tea districts, each one independent locally, but all affiliated to some centre, and all bent on carrying out the same rules, which shall have for their object the general good of the industry and not the furthering of private interests. Then a coolie who breaks his agreement without just cause, will have his descriptive roll sent to each garden, and will find it utterly impossible to obtain employment. He will thus be compelled to go back to the planter who imported him at [illegible] he entered into an agreement for a [illegible] of this sort will put a stop to deserting voluntarily, or with the help of the sections of Act VII. We need not enlarge on this subject, as we imagine we have said enough to point the moral of unanimity and union.

THE SALARU FARM.

THE report on the Government Farm of Salaru for the half-year ending 30th April 1880, has recently been issued, and if nothing else has been effected, a clear proof of the benefit of deep ploughing has been adduced. But we do not get all the information we should like, and which is necessary to enable us to form a clear opinion on the point. For instance, we are not told how the ordinary country cattle managed to drag the English ploughs, nor is a word said as to the relative depths of the furrows as compared with those of the ordinary country *hal*. The experiment referred to was made with *bajri* and cotton. The field selected for the *bajri* experiment, was one overrun with a perennial grass crop, and while this was naturally against a good yield of grain under ordinary circumstances, it served the more clearly to prove the value of the work done by the English plough. The great difference between the English and native ploughs is that the former gives a deeper furrow, and besides it does what is never attempted by the native implement—it completely inverts the mould. Two advantages accrue from this—a new stratum is exposed to atmospheric influences, and the roots of perennial grasses and weeds are exposed to the action of the sun. Thorough exposure to the atmosphere constitutes the best manure the farmer has at his command, and it is one which after all does not cost much. Instead of ploughing so many beegahs per day, according to the cattle power at his command, if the rayat would only do, say two-thirds as much, and do it deeper, he would be astonished at the result. The country plough scratches the soil, and exposes the roots of the weeds to atmospheric influences thus fostering their growth in a remarkable degrees, while the stratum of soil which he actually loosens and leaves to a certain extent to be acted on by the air, is the same stratum which has done duty in this way for centuries, and which has as little humus in it as a handful of sand. With regard to the grass and weeds, the mould board of ploughs on the English system completely inverts the soil and exposes the roots inverted to the influence of the sun, which speedily deprives them of their germinating power. The plough used at the Salaru Farm was a Howard's English, and must of course have been of very light draught, turning over the soil to the depth of perhaps $3\frac{1}{2}$ to 4 inches. We should have liked definite information on these points, and also as to whether the draught was within the reach of the ordinary country bullocks, without having to increase the number of cattle yoked to the plough. In the case of the crop of *bajri*, the result was so satisfactory as to be decisive.

The following table will give at a glance the results:—

	Scinde plough.	English plough.	Excess of English plough over Scinde plough.	
	lbs.	lbs.	lbs.	Percentage.
Grain ...	1,059	1,578	519	49
Straw ...	3,215	4,139	1,224	38

Otherwise than in the matter of ploughing, both plots were treated exactly alike, both having received two artificial waterings.

Now we turn to the cotton. Two acres were ploughed with the English plough, and five acres with the ordinary village implement. In other respects the plots were treated exactly alike, and the results obtained were as follows (in lb. of uncleaned cotton per acre.)

	Scinde plough.	English plough.	Excess of English plough over Scinde plough.	
	lbs	lbs.	lbs.	Percentage.
Uncleaned ...	1,164	1,561	400	34½
Equal to cleaned	388	521	138	31⅓

The value of the excess 133lbs., was Rs. 28-10-4, it having actually sold for this sum, while the cost of the extra deep ploughing was Rs. 5-5-7, leaving a clear gain of Rs. 22-4-9 per acre. And this is not all. The improvement resulting from the deep ploughing will be found to be permanent, and future crops will derive benefit from it. In this way the value of the land will be improved.

During the half-year under notice, sundry other experiments were entered on, but as they do not seem to have been followed up carefully, they were bare of useful results. For instance, in one case, village cattle were permitted to destroy a crop, and surely where the exact results of experiments are aimed at, such a contretemps should have been prevented. The experiments with different manures gave much less of a valuable residue of results than did the deep ploughing trial, and we would strongly urge on cultivators, both of cereals and perennial crops, such as teas, coffee, &c., to give a large amount of attention to deep cultivation, where of course the soil is suitable. Where the subsoil is cold and sour, it would be ruinous to bring it up to the surface, but where there is a fairly good subsoil, as is the case in most cereal soils and in almost all tea soils, the advantages of deep ploughing and hoeing cannot be overrated.

EDITORIAL NOTES.

With the view of promoting agricultural improvement in Bengal, and encouraging the study of scientific agriculture, the Lieutenant-Governor has determined to create annually two special scholarships of £200 a year each, to be held by science graduates of the Calcutta University at the Royal Agricultural College, Cirencester. The first two scholarships will be tenable for two and-a-half years from the commencement of the January term in 1881. Only natives of Bengal, Behar, or Orissa, who have passed the B.A. examination on the Physical side, will be eligible. An allowance of Rs. 1,000 will be made to defray the expenses of each scholarship-holder in proceeding to England, and a similar allowance will be made for the return journey on the completion of the course. Applications will be received by the Director of Public Instruction, and will be submitted to Government with a report from a Committee consisting of the following gentlemen: The Director of Public Instruction, Mr. C. H. Tawney, Baboo Bhudev Mukerji, C.I.E., and Mr. A. W. Garrett.

With reference to the Indian Famine Report, just issued, it is stated that the questions of tenure irrigation, railways, &c., will be dealt with exhaustively in the second part of the report, which will, it is hoped, be ready for presentation to Parliament, before the close of the session. The first part of the report relates to famine relief; the second deals with the measures by which Government, through its action, may place the people in a better condition to withstand the effect of droughts.

We have before us the last General Administration Report of the Patna division, from which we learn some of the excellent results that have attended an increased cultivation of the sugarcane. Canal irrigation has done much by reclaiming and fertilising waste and barren lands, to develop the area under sugarcane, especially in the Gya district and in the Jehanabad sub-division. In the latter district the canal water, by means of the great facilities it afforded to the cultivators, has given a great impetus to the sugarcane industry. The results of last year's operations, we are told, paid very well, and there is no reason to doubt that the cultivation of sugarcane will continue to extend in the immediate future. Some remarks of the Sub-divisional Officer of Jehanabad are especially noteworthy, and we shall reproduce them here in the shape of a brief extract. He says that :—

"A ryot has made a clear profit of Rs. 80 per beegah by sugarcane. Comparing this with the sum of Rs. 8, which is considered to be a good profit in a beegah of *rubbee* or *khureef*, and that of Rs. 20 which poppy yields, there can be no doubt that sugarcane is the most valuable crop, and that an extensive cultivation of it is more likely than anything else to raise the condition of the ryots. There are no doubt certain drawbacks, namely, that the crops remain longer on the ground than any other, and that the work of preparing the land and irrigating the crops is extremely arduous. Still, the cultivators say that it does not require the same unvarying and engrossing attention that poppy cultivation does. It has been found that the sugarcane has in some places superseded poppy cultivation."

It will be seen that some most important statements are contained in the above paragraph, and we shall be glad to hear of further attention being paid to the subject. Many improvements have been made of late in connection with the sugarcane industry in Bengal. Experiments in agriculture have been carried out by European and native gentlemen, of practical knowledge, and new machinery has been invented and introduced in some parts. Conspicuous among these have been the gentlemen in charge of the Beheea estate—Messrs. Burrows, Mylne, and Thompson—whose new sugar-crushing machine, by reason of the great saving it effects in the outturn, is destined apparently, soon to be universally adopted. According to the Lieutenant-Governor these gentlemen, by their experiments, are "rapidly revolutionizing the whole (cane) sugar industry of Bengal."

Perhaps the most marked instance of success in the way of improvements that do not interfere with the rayat's prejudices is Messrs. Thomson and Mylne's Beheea mill. An improved cane-crushing mill was called for, and these gentlemen responded to the call, with the most gratifying results to all concerned. Their mill has many points to recommend it: first, it is simply the old native mill improved upon, and this is a strong point in its favour. It does not look like an English mill, but has all the characteristics of the old country mill the *kolhu*. Then it takes no more power to drive it, no more bullock power we mean. It would doubtles be easy to construct a mill which should do its work in a very complete manner, if no limit were placed on the power necessary to drive it, but with the average rayat, this is all important. He has a certain amount of bullock power at his disposal, and if you make a demand on him beyond this amount, you at once call on him to make an extra outlay to which he objects. The Beheea mill is worked with the same bullocks which worked the *kolhu*. That is another strong point gained. The patentees claim for it the advantage that half the number of bullocks suffice as are necessary for the other, but to be safe we will say that no more power is required. Then the *kolhu* being a fixture, necessitates all the cane being conveyed to it, whereas the Beheea mill can be moved by four men from field to field, a great saving in cartage being thereby effected. It does not require so many attendants to work it. For the old mill the cane has to be cut into short lengths, and as at the ends of each length fermentation is apt to supervene, it is easily understood that the quality of the juice is prejudicially affected thereby. The Beheea mill takes the cane whole, thus saving the labour of cutting and obviating the chance of fermentation. The juice from the latter sells therefore at 25 per cent. higher price than the other. Besides this, the rollers having more grip, the percentage of juice is larger than from the *kolhu*. Against all these advantages, there is only the drawback of increased cost. The prices are from Rs. 80 to Rs. 95, according to size, a sum considerably higher we presume than the cost of the other, but this does not weigh as a feather in the balance with the rayat, when he sees that this extra cost will be more than recovered in the course of a single season. Consequently we are not surprised to find that over nine thousand of these mills have been purchased in the Shahabad district alone.

We have repeatedly pointed out the absurdity of India purchasing sugar from other countries, when she can grow it so well herself, and we have also made the same remark regarding other articles. A few such successes like that of the Beheea cane crushing mill, and we shall have no cause for complaint left.

A Circular has been addressed by the Director of Agriculture and Commerce in the North-Western Provinces to all persons interested in the improvement of agriculture. The circular makes some very important suggestions, which we make no apology to place before the reader. In the first place the liberal use of bone dust as a manure is recommended. The circular says :—"The great increase in produce which results from the use of crushed bones as manure seems quite unknown to the people of this country, although in England bone dust is extensively

used and paid a high price for (Rs. 3 a maund). On the Cawnpore Farm, during the last *rabi* season, bone dust applied at the rate of 3½ maunds to the acre, gave a wheat crop of nearly 24 maunds of grain and 35 maunds of *bhoosa* to the acre which was 8¾ maunds of grain and 15 maunds of *bhoosa* more than was gained from unmanured land."

The crops for which bone dust will be found most useful are, maize, sugarcane, wheat, and barley. Then we learn that the urine of cattle is a far more potent manure than their dung. The circular says :—" In Europe it is carefully collected by keeping bedding of grass or straw under the cattle in their sheds, which absorbs all the urine as it falls, and which when rotted is applied to the land as manure. In this country it is inadvisable to use bedding since in the hot weather and rains it harbours insects and rots the feet of the bullocks, but I recommend that an attempt be made to collect cattle urine in the following manner. Have the floor of the bullock shed sloped off to a pit in one corner, and well rammed with clay, so as to let the urine drain off it into the pit. Keep the pit half filled with loose earth, taking out as much of it as is saturated with urine, say, once a week, and replacing it with dry earth. The earth saturated with urine should be kept for 3 or 4 months, and then applied to one-half of a field, and its effect in increasing the produce judged of by comparison with the other half."

Deep cultivation is highly recommended. The chief difference between the Indian and European methods of tilling the soil lies not so much in the *depth* to which the soil is cultivated, but in the fact that the European plough *turns the soil right over* while the Indian plough merely stirs it. Most European ploughs are meant to be drawn by horses, and are too heavy for bullocks, unless two or three pairs are yoked. But a plough on an American model has, we learn, been adopted by this department which is very light, cheap, and simple and which with an ordinary pair of bullocks will plough to a depth of 5 inches and turn the soil completely over to that depth. Many district officers and native gentlemen have used this plough, and given very favourable accounts of it. The Agricultural Department, we learn, is willing to lend ploughs of this kind for trial on application.

The Bengal Government has granted a sum of Rs. 2,000 for the importation of good potato seed from England and Australia, which on arrival is to be planted at Kalimpoong. Some years ago Darjeeling used to be famous for the excellence of its potatoes, and a very considerable trade in this produce with Calcutta and other places existed. Of late years the Darjeeling potato has been steadily deteriorating in quality, and the export trade which formerly existed has in consequence become almost extinct; Calcutta being now almost exclusively supplied with Bombay potatoes. The deterioration of the Darjeeling potatoes is apparently due to the native *jhooming* system of cultivation having become impossible in this district of late years, to the use of inferior seed year after year, and to the native cultivators knowing nothing about the rotation of crops, and never manuring the ground before sowing. The usual practice with the native cultivators is to sell the largest and best potatoes and to reserve only the smallest and worst as seed for the next season's crop, with the inevitable result of yearly deterioration both in quantity and quality. The introduction of a new and improved strain of seed in this district is calculated in time to restore a trade which has, owing to the causes above enumerated, almost ceased to exist, and it may safely be predicted that Government will in a very short time recoup itself for the Rs. 2,000 sunk in the very laudable effort to encourage the cultivation of a better class of potato by the hill people. That really splendid potatoes can be grown in the Darjeeling district is very well known, and the fact has been proved by a local gentleman, who imported some seed from Messrs. Sutton at the beginning of the year, and who planted it out on carefully prepared land. The crop is now being dug, and the results are more satisfactory, the potatoes being fully equal, both in quantity and quality, to English grown potatoes.

The *Pioneer* says that "the Government of India has ordered the extension of poppy cultivation to the Agra, Muttra, Aligarh, and Moradabad districts of the N.-W. Provinces, in addition to an increase in the area in districts where the cultivation at present exists. A considerable increase in the staff of the department, European and native has also been sanctioned. Mr. H. Rivett-Carnac, C.I.E., the Opium Agent, to whom the necessary measures have been entrusted, is now on tour, arranging in communication with local officers, the details of the new scheme."

The Lahore paper publishes a long letter on the Hissar Cattle Farm, and the vast improvements it has undergone under the able management of General Angelo. Beneath his fostering care, the writer tells us, jungles have given place to luxuriant and neatly kept fields, order has ousted disorder, neatness taken the place of untidiness, and economy that of lavish expenditure. He has initiated a new of system of ploughing and cultivation, to see which the zemindars not only flock in crowds to Hissar, but of which they have expressed their approval by adopting it themselves.

The news from the Berars is very bad, we are sorry to say; the clouds are carried over the country by strong westerly winds and no rain falls. A six-anna cotton crop is the utmost that is now hoped for.

A *Daily News* telegram from Alexandria states that the cotton and other crops in Egypt are looking splendid, and that the Nile promises to be equal to last year. Land is increasing in value.

When we are hearing such an outcry from most quarters regarding what is called " the deplorable state" of Indian trade, says the *British Mercantile Gazette*, it is well to look into the facts as represented by recent statistics. As for the financial blunder, that belongs to a totally different aspect of the question, but looking at the returns regarding India's foreign trade, there is no evidence of retrogression, but of steady progress, only temporarily interrupted by the universal depression. During the last ten years the imports of merchandise into India have increased 25 per cent., and transactions in cotton manufactures have gone up 50 per cent. The exports during the same period have increased over 20 per cent. Jute, hides, and skins, opium, grain, seeds, particularly represent a fair increase; but the most remarkable figures are in regard to tea, which has improved 200 per cent. during the last ten years.

The weekly report of the Bombay Chamber of Commerce just issued, gives the details of the trade for the first seven months of the year :—

		1879.	1880.
Cotton	... bales	551,978	816,036
Wool	... "	40,228	59,506
Linseed	... cwt.	421,931	1,400,318
Wheat	... "	8,590	1,075,509
Coffee	... "	90,969	106,895

It will be seen that cotton has increased 48 per cent., wool 47 per cent., linseed 230 per cent., wheat 12,304 per cent. (!) and coffee 18 per cent. No little part of the enormous increase in wheat shipment is owing to the opening of the short distance of the Rajpootana railway. The *Bombay Gazette* says there is still a good deal of wheat and seeds to go forward, and the stock of cotton in Bombay is much larger than for many monsoons, so that prospects for the rest of the year are encouraging.

Ceylon promises to make a good show at the forthcoming Melbourne Exhibition. Tea, coffee, cinchona, cacao, and cinnamon will be among the chief agricultural products, while in the ranks of manufactures the cabinet work of the Kalutara and Galle carpenters will stand well to the fore. Mr. A. M. Ferguson, senior editor of the *Observer*, who goes as the Ceylon Commissioner, carries with him the confidence of all classes, and there is no doubt but that he will do full justice to all Ceylon interests committed to his charge. The Madras specimens have been sent to Melbourne, and, according to the catalogue pub[illegible] they ought to attract some notice.

Prof. Baeyer has, says the *Athenæum*, discovered and patented a method of obtaing artificial indigo, which is to be worked on a commercial scale by the Baden Aniline Company. The indigo is obtained from chloride isatin which is produced from benzole.

The Rangoon trade in salt shows considerable improvement annually. During the past official year, says the *Gazette*, 1,430,208 maunds of this article were passed through the Custom House for consumption on payment of a duty of

Rs. 1,71,816, while in the year previous, 1878-79, only 905,712 maunds nett, yielding a duty of Rs. 87,697, were consumed. Of the first mentioned quality, 894,323 maunds were consumed locally on payment of a duty of Rs. 1,67,686, at the usual rate of 3 annas per maund, and 535,885 maunds were exported to Upper Burmah and charged with duty at one per cent. of the market value of the commodity under the provisions of the Treaty of 1862. The latter quantity then paid the nominal tax of Rs. 4,130 only, whereas if charged with duty at the usual rate the amount collected thereon would have been Rs. 1,00,479.

NEW rice mills are still the order of the day in Rangoon, amongst both European and native firms. Three new ones are being put up now, and are expected to be ready for working by the next rice season; and we believe one additional rice mill is to be started in both Bassein and Moulmein. Improvements in rice machinery are yearly effected, and with the rapidly extending demand for cleaned Burmah rice in China and South America, there will doubtless be profitable trade for all the new erections in a few years. It is to be regretted, however, that the mercantile community do not interest themselves more in the land question, and move the Government to make more liberal grants of waste land, for the purposes of cultivation. There is no doubt a more liberal system would attract to these waste lands the population and capital which are now confined to the large towns, and if new rice mills continue to be erected in the numbers that they have been of late years, the difficult question for their owners to decide will be where to get sufficient supplies of grain to keep them constantly working. It would, therefore, be advisable for the merchants to look a little ahead, and to do all they can to encourage an increased cultivation of rice, or they may find in a few years that they have gone so far ahead of the present capabilities of the province, that their mills will be forced to remain idle for a great part of the year owing to the inability of the present population to supply them with paddy or unhusked grain in sufficiently large quantities. The capability of the soil may be boundless, but with the slow rate of increase amongst the agriculturists, which may be put down to the restrictions, red tape, and routine which has to be gone through to acquire land for cultivation, we may shortly find that the milling power in Rangoon is enough to convert the whole produce of the province into rice in a very few months of the year.

OUR Rangoon correspondent writes to us:—Government recently despatched a model of a Burmese kyoung or monastery to the Melbourne Exhibition. Had specimens of our lacquered-ware, silver workmanship, rice and tobacco been sent, I think it would have given the colonists a better idea of the province, and possibly induced some orders from Australia to our merchants and traders. Tea from Arakan and coffee from Tonghoo might also have been exhibited. Both are of the finest quality, and it is greatly to be regretted that unwise land legislation keeps the cultivation of both products backward. Surely to encourage the cultivation of such valuable articles for export, Government might offer land, of which there is such abundance here, free to any company or private person who could shew they possessed adequate means for cultivation, and on such terms that if the land was not used for the purpose it was applied for, or a certain proportion not brought under cultivation within a certain number of years, the land would be liable to be resumed. It can only be by some such liberal terms offered to the first in the field that we can hope to attact capital and population to this province. This has been pointed out over and over again, but still the Government made no move, and only offer leases where they should gladly make a present of the free hold to induce capitalists to come forward.

THE experiments of jute cultivation that have been carried on lately in Brazil are likely, it is said, to turn out a success. Both the soil and climate of the Brazilian lowlands are well fitted for growing jute; in some places two crops a year are obtained. The fibre of the Brazil jute is said to be of a superior quality; and the Brazilians are prepared not only to grow the raw material, but also to start manufactories.

THE *Lucknow Times* gives the following interesting account of the growth and manufacture of Chinese white wax:—

The white wax of Sze-chuen, China, is most peculiar in its growth. We observe that Baron Richthofen estimates the value of the annual crop, on the average at about £650,000. In 1879, upwards of £81,000 worth of this curious entomological secretion was exported from the one port of Hankow alone. White wax is the mere exudation of an insect in a state of disease, aggravated probably by the operation of an uncongenial climate, and favoured by the presence of a tree for which the creature has an affinity. In the Keenchang district, an evergreen, known as the *ligustrum lucidum*, thrives in abundance, and on its twigs in the spring of the year countless flies swarm like a brown film. The branches soon become covered with a white, soapy incrustation that increases in volume until the commencement of the fall of the year, when the sprays are cut off and immersed in water, which is kept boiling. The viscid substance rises to the surface, and is skimmed off, melted, and allowed to cool in deep pans. It was accidentally discovered that by transporting the insects from their native district to the more vigorous one of Keating Fu, in the north of the province, their capability of discharging wax was largely augmented, a property which was promptly and extensively availed of by the Sze-chuen traders. The period between morning and evening is chosen for conveyance, because many hours of sunlight would percipitate the hatching. This should take place only after the females have been attached to the trees. Arrived at their destination, six or more of the mothers—which are enormously prolific—are tied, wrapped in a palm leaf, to a member of the *ligustrum*. A few days later the young flies are swarming on the twigs, where they fulfil their mission by the month of August. Then they perish in the caldrons, where the results of their brief existence are collected. It is said that this peculiar industry requires the exercise of great care, forethought, and experience.

A DUBLIN paper, the *Farmer's Gazette*, says that the durability of wooden posts planted in the ground depends in a great degree on whether they are planted in the position in which they grew or *vice versa*. Owing, it is supposed, to the moisture not being able to ascend against the grain, posts planted top downwards remain sound many years longer than those not so reversed.

SELECTIONS.

THE MUDDAR PLANT.

A MEMORANDUM on materials suited for paper-making that we have received from the Agricultural Department, contains a most interesting monograph on the above weed.

We use the term "weed" advisedly, for though gifted with almost every quality that can make it useful to man, the Muddar still continues a useless jungle plant, that can be viewed in almost every part of India from the windows of a railway carriage—a standing example of how much yet remains to be done before the much-talked of development of the resources that lie at our feet, becomes an accomplished fact. The whole of Rajpootana so far as we have seen it, may be called a Muddar preserve; the plant abounds all over the Punjab and the N.-W. P., is found in moist and marshy Bengal (we have seen a splendid specimen of it in a compound in Calcutta), occurs again in Madras and Mysore, everywhere in fact where there is soil on which to grow, and where no care is required for its growth. In the words of the Report before us, it will grow where nothing else will grow—on beds of sand for instance. But it is equally at home on rich soil; a perfect cosmopolitan in short, that presents itself everywhere whether it is wanted or not, and always with a kind of mute reproach expressive of—"Why do you not make use of me? You could easily do so if you would only take the trouble, in place of frittering away your time on other plants that have not half the good qualities which I possess."

We must confess the Muddar is a perfect pariah amongst plants. Nobody takes care of it, for it takes such good care of itself that it is looked upon rather as a nuisance by those who have an eye for the picturesque. Its tough sea-green leaves are suggestive of leather, and it is only while the pods are bursting and the silky contents floating about upon the wind that the plant can lay any claims to beauty. But that is a matter of opinion. The homely useful qualities of the weed we shall attempt to describe as briefly as possible in the following lines.

So far back as 1852 Dr. Riddell, Officiating Superintending Surgeon of his Highness the Nizam's Army, came to the conclusion that the milky juice of the Muddar, was not unlike guttapercha. After drying, he tried experiments with it in acids, alcohol, liquor potassm, and spirits of turpentine, and the tests corresponded exactly with the established results of the real guttapercha. Captain Meadows Taylor of the Hyderabad contingent on hearing of these experiments tried another test. A piece of the real guttapercha of commerce and a piece of the new substance, both of the same size, were softened in hot water and united readily. He then submitted the mixed substance to a test by acids, and the results did not differ from those on either of the two original separate substances. In May 1853, Captain Hollings, Deputy Commissioner of

Shahpur in the Punjab, obtained precisely similar results with the juice of the plant grown in that province. He also used the Muddar guttapercha, instead of silk, for isolating wires used for the conveyance of electricity, and he found it to answer very well He placed a wire covered with the substance in a brass vessel filled with water, and found that the electric spark was carried along the inner wire without interruption. Dr. Riddell sent some specimens of the new guttapercha to be examined by a chemist in London, who put it into the hand of a scientific gentleman, Professor Redwood, who said :—" The substance resembling guttapercha, obtained from the Muddar, I find possesses several properties in common with guttapercha, while in other respects it differs." He tried to vulcanise it (*i.e.*, to combine it with sulphur) but did not succeed, and he did not think it could be deprived of its property of being a conductor of electricity.

No further attempt has been made to solve this problem for more than a quarter of a century!

The next good point about the Muddar is the toughness of the fibre yielded by its stems. Ropes of surprising strength can be made of it, and it is also suitable for weaving as it blends readily with silk. Fishermen in Sind use it for their nets, and the hillmen in the Rajmahal Hills use it for their bowstrings, which are said to last five years in constant use and exposed to all kinds of weather. Some twine made from this (the Rajmahal variety) bore 248lbs. and 343lbs. in the dry and wetted conditions, when hempen twine of the same thickness bore only158lbs. and 190lbs. in the same conditions. Some experiments on the Madras variety again showed that it bore 532lbs, when the *sunn* of Coimbatore bore 407lbs., the *agave* (aloe) 362lbs., cotton 346lbs., and coir 224lbs. only.

The extraction of the fibre is the difficulty. It has to be picked off the inside of the bark, *not* from the stem itself. Captain Hollings says :—

" The workmen bite through the bark about the centre of its length; they then hold the tissue of threads in one hand and separate the bars with the other. I have tried hot and cold water, and all the arrangements known for the separation of hemp, or rather the preparation of *sunn* jute, &c., without success; as yet human teeth and nails are the manipulators, but it is not unreasonable to suppose that some chemical process will be discovered by which the bark will be easily separated from the fibre."

In 1855, practical men in England pronounced the fibre to be well calculated for supplying the place of good flax for making prime yarns, and it was considered at that time to be well worth from £30 to £40 per ton. Here too nothing has been done to improve the methods of extracting the fibre for the last quarter of a century.

The third product of the Muddar is the smooth glossy cotton, yielded by the bursting of the pods, and which resembles short lengths of pale yellowish-white floss silk. In France and Germany this has been worked up into articles of dress, and Messrs. Thresher and Glenny also succeeded in manufacturing a texture composed of equal parts of Muddar floss and cotton, and also a flannel from Muddar in one part and wool two parts. In October 1849, Mr. Mounckton, C.S., of Etawah, sent to the Agricultural and Horticultural Society of Bengal some specimens of cloth manufactured from the Muddar cotton. In one of these the warp or longitudinal thread was of common cotton, and the weft or cross ways of pure Muddar. In other specimens the warp was half common cotton and half Muddar, and the weft three parts Muddar to one of common cotton. At the International Exhibition of 1862 the Shahpur Jail gained a medal for its manufacture of Muddar cotton stuffs. And in the Punjab Exhibition some table napkins were exhibited made of Muddar cotton in Dehra Ismail Khan, also towels made of Muddar and ordinary cotton mixed, also a rug made of Muddar (coloured) from Rawal Pindi.

We have now said enough about the products of this valuable plant. It only remains to add that its cotton is supposed to be peculiarly well adapted for paper-making, and that it is probably in this direction that the Muddar will first be utilised. As his Highness the Maharajah of Gwalior has set an example of enterprise in starting paper mills, he may as well follow up his venture by bringing into use a material which can be had for the picking over a great part of India.—*Delhi Gazette*.

THE RAINFALL OF INDIA.

THE rainfall in India varies greatly. Cherapunji, on the Khasia Hills, north-east of Bengal, has the heaviest known rainfall in the world. Rain is estimated in inches. Every inch multiplied by 14½, represents the number of millions of gallons which fall per square mile; each gallon weighing 10lbs. At Cherapunji the rainfall averages 521 inches a year. This means that if all the rain which falls there during a year remained on the ground, it would form a lake 43⅜ feet in depth—sufficient to cover a large house of two stories. On the other hand, in Upper Sindh the average rainfall is only about two inches a year, while sometimes a twelvemonth passes without a single shower. Between those two extremes, there is every intermediate gradation.

The rainfall in India is greatly influenced by the monsoons, or periodical winds which blow alternately from the south-west and the north-east. The South-West Monsoon, lasting from May to September, causes two belts of excessive rainfall. One extends from the mouth of the Irrawaddi along the east coast of the Bay of Bengal, up to the valley of the Brahmaputra, and along the skirts of the Himalayas. The other streches along the west coast of the Peninsula, from the seashore to the summits of the ghâts. In both cases, wind from the Indian Ocean, highly charged with vapour, drives against the face of a mountain range. The air in rising expands and is cooled, precipitating therefore a considerable part of its vapour. The rainfall increases with nearness to the hills in the direction of the wind. Thus at Lahore, 100 miles from the nearest hills, the annual rainfall is 15 inches a year; at Rawul Pindi, near the foot of the hills, 29 inches, and at Hazara, on the hills, 44 inches.

On the *lee* side of a range, that is, on the side opposite that on which the wind blows, the rainfall is comparatively small, the air losing its vapour in crossing the mountains. At Bombay the annual rainfall is 71 inches; at Mahableshwar, one of the highest points of the Western Ghâts, it is 260 inches, while at Poona it is only 27 inches.

Madras draws its chief supply of rain from the North-East Monsoon. The wind in its comparatively short passage over the Bay of Bengal, does not collect the same amount of moisture as the South-West Monsoon. The avarage rainfall at Madras is about 49 inches a year.

On the west coast most rain falls from May to August; in the Carnatic October and November are the wettest months.

In the north-west corner of India there is an arid region, including all Sindh and half the Punjab, where the average annual rainfall is less than ten inches. Next, there are two zones of dry country, with an annual rainfall between 15 and 30 inches. One, named the Northern Dry Zone, surrounds the arid region in the north and east, in a belt from 100 to 200 miles wide. It includes Delhi and Agra. The Southern Dry Zone is in the peninsula, extending from Nasik to Cape Comorin at a distance between the two seas. The next region has a rainfall between 30 and 60 inches, and includes the upper part of the valley of the Ganges, Central India, and the eastern coast of the Madras Presidency. The deltas of the Mahanadi and Ganges, and the lower part of the Ganges Valley have a rainfall between 60 and 75 inches a year. The coast of Burmah and part of the west coast of India have a rainfall of above a hundred inches a year.

The rainfall of a few other places may be mentioned.

The highest known rainfall at Calcutta for 3? years was 93 inches; the lowest but one, 44 inches. The average is 66 inches. According to Parkes, Benares has, on an average, 37·4 inches annually; Agra, 28 inches; Delhi, 25; Meerut, 18; Nusserabad, 15·8; Peshawar, 13·7.

At Madras* the highest known rainfall for 67 years was 88·41 inches; the least was 18·45; the average 48·56. The rainfall at Moulmein is said to be about 180 inches a year.

Colombo, Galle, and Kandy, in Ceylon, have nearly the same annual rainfall,—about 80 inches a year. The rainfall in the north of the Island is only about half that on the south-west coast. At Ambagamuwa, the average is about 200 inches a year.

THE GROWTH OF BARLEY.

I WAS much struck with two letters which appeared in your valuable journal some weeks ago, the first from INQUIRER, asking for information from some of your numerous readers, respecting the barley crop of 1879; the other letter, signed BOTHERLY HELP, quoting an extract from a speech of Mr. Gladstone's, in which he rebuked farmers for the want of mutual interchange and communication of successes and failures in their business. As a proof how well we farmers deserved the rebuke, we find but two of our *profession* troubling themselves to give the asked for information. If the details of the different experiments made by many of us were given in our agricultural papers (of which we consider yours one of the best) much time and expense would be saved to many beginners, as they then would have simply to refer to their extracts from your Journal, and find whether or not their idea was worth trying. With your permission I will set an example by giving you a few of the wrinkles I have learned during the last thirty years in preparing the land for growing the best quality of malting barley, which is, from all accounts, to be one of the principal mainstays of the British farmer for years to come, the area where it can be grown being so small, and the demand likely to be large as soon as trade revives and our mechanics have plenty of spending money.

On no single subject connected with farming have I found such a diversity of opinion as on the preparation of land for the barley crop. If we take the Norfolk farmers for example, you will find one who will follow with his plough immediately after the sheep fold, just turning over the land with a furrow two inches deep, his neighbour will break his land up six or eight inches deep, with a plough without a breast. This will leave the dro[illegible] near the surface as his neighbour has done, and besides, will, by breaking up the [illegible] rendered it less likely to suffer from heavy rain or drought. They both will follow with

* The following statistics may interest some of our readers. Average monthly rainfall at Madras; January, 0·95; February, 0·28; March, 0·44; April, 0·68; May, 2·37; June, 1·99; July, 3·79; August, 4·53; September, 4·74; October, 10·84; November, 18·97; December, 4·98. *From Madras Observatory.*

The *Madras Administration Report*, for 1877-78, gives the average rainfall of the districts for ten years previous to 1876-77:—Bellary, 22·34 inches; Coimbatore, 23·71; Tinnevelly, 26·91; Kurnool, 27·33; Cuddapah, 28·01; Madura, 28·81; Kistna, 30·41; Nellore, 33·47; North Arcot, 33·83; Salem, 34·66; Godavari, 36·49; Trichinopoly, 37·06; Tanjore, 37·87; South Arcot, 38·29; Ganjam, 40·48; Vizagapatam, 41·01; Nilgiri, 44·68; Chingleput, 50·64; Madras, 53·33; Malabar, 107·95; South Canara 136·60.

another ploughing just previous to drilling the barley. The second is the system from which I have seen the best results. Again, you hear another light land farmer as strongly recommend ploughing but once after the sheep fold. This may answer in a favourable season, when your land suffers from neither heavy rains nor droughts, but it is not one that I would recommend. Then, with respect to the mixed soils and so-called heavy lands of Norfolk, you find just the same variety of opinion. My experience, and what I could learn from successful barley growers, convinced me that it was necessary to get the major part of the land folded and ploughed up before Christmas, giving it one fair earth of some five or six inches deep, then letting it lie until the latter part of March. Then scarify it across the furrows, harrow, and drill from six to eight pecks of the best barley you could obtain, and hope for the success you deserve. By the coast you find still another plan in operation. They grow heavy crops of swedes and white turnips, all of which are carted either on to the wheat stubbles, and there thrown about for the bullock to blow themselves out with, or are carted home and given without stint to the bullocks in the boxes. The land is then ploughed once, and sometimes twice, about three inches deep. Then in April they drill from three to four bushels of barley per acre, and, as any one out of the district would suppose, they grow a heavy crop of weak soft straw, with an equally light crop of inferior barley. One or two outsiders adopted the plan of feeding a third of the roots on the land, then first ploughing it six inches deep without the breast, and afterwards about four inches in the usual way; drilling in March from eight to ten pecks per acre, with a marked improvement both in quantity and quality.

The system of growing barley after wheat has very much increased of late years, neither the crops of straw nor corn are so heavy as after roots, but the quality of the barley is generally much superior and more suited for malting purposes. The cultivation found to answer best is ploughing the wheat stubble in, soon after harvest, then another earth in January or February, the manure being applied during the frosty weather. If any artificial manure is used, it might consist of two to three cwt. of superphosphate and one cwt. of nitrate of soda.

The growth of barley on heavy clay lands has also come more into favour since the price has increased, and that of wheat decreased. The usual cultivation is as above, if it is grown after wheat; and if after dead fallow, the land is summer-fallowed in the usual way, mucked in autumn or winter, and again ploughed during the winter. The best time for this last operation is when there is a frost, which will require to be very severe to prevent one's getting on with this work; the land will then fall down like lime, and take but little working when the barley is drilled. Two cwt. of superphosphate will improve the quality of the crop.—*Cor., L. S. Journal.*

ABOUT PAPER FIBRES.

WERE we to ask any ordinary reader what paper is made of, the answer would probably be promptly "rags, of course." This is so nearly correct that if it be recollected as the leading idea in the subsequent remarks on materials for paper-making, they may prove interesting, if not, also useful. The Government have for some time been inquiring as to India's capabilities for producing such materials, and the results of those inquiries in all parts of the country have been curious and will probably be utilised by commercial people.

We associate the word "rags" chiefly with cotton and linen rags rather than with woollen. Woollen is unfitted for paper-making, but the other two materials well represent almost all others. The one, cotton, is a fibre derived from the "seed-vessels" of a plant: the other is fibre from the "stock" of a plant. Cotton is the commonest material, and India is the home of cotton. Then, say some, the question is settled, 'let India sell cotton to the paper-maker.' But this will by no means do. The paper-makers cannot afford new cotton; old rags easily collected are good enough for them, and the price is incalculably cheaper. It will not do even to send refuse waste home. The question is, is there no other cheaper source of fibre in the jungles or deserts of India, which will pay to collect and export.

Our first inquiry is, what are the exact requirements as regards such a fibre. This is answered by the curator of the Victoria and Albert Museum, Bombay. "To be successful, a raw material for paper-making should possess certain qualities. The first and most important is an abundant and lasting supply easily procured, and cheaply prepared for exportation, nor should its bulk be too gre[illegible] when in the hands of the paper-maker, it should work up [illegible]y, and at a moderate cost, and present no difficulties in bleaching: a fibre should have a certain amount of roughness to enable it to 'felt' or cohere in the massy, and lastly it ought to turn out at least 50 per cent. of good marketable paper."

First, as regards "an abundant and lasting supply," it is unlikely that it will ever pay to cultivate good land for this special produce, unless systematic paper manufactories were started in India itself. To this point we shall afterwards revert. But it appears from the various reports returned to Government that some of the best fibres are produced on land otherwise useless. Some grow in thick trackless jungles: some, such as the bamboo, in endless forests in difficult tracts; others, such as the *muddar* and certain grasses, in ground otherwise perfectly sterile and desert; and others in equally useless swamps and marshes.

This then, to start with, is very hopeful. It is said that the wise, good hearted Linnæus defined a *weed* as "a plant whose virtues and uses have not yet been discovered." If the weeds of our immense deserts are discovered to be useful articles of commerce as regards the important art of paper-making, weeds merely waiting to be gathered and sold, no doubt an impulse will be given to investigation in many other similar directions. The question of bulk in packing is of course an important one as regards cost of transport and freight, but, if the fibre is worth having, doubtless processes would soon be invented to eliminate the rubbish from the useful part and economise the bulk of the latter, just as in the wool-trade it is the most economical plan to clean it before despatching it to consignees, who do not wish, if they can help it, to pay freight for filth, mud, and refuse. The bleaching is more a question for the manufacturer than for the collector of the fibre, because if it is good for bleaching at all, the maker perfers to do it himself, from the beginning of the process. This therefore need not trouble the exporter: what he has to see to is that the fibre is what the maker will buy.

The question of "felting" of the fibre is a curious one to those who have never seen a paper mill. It is not a question of long or short fibre, or of fineness or coarseness. It is not whether it will make fine tough threads or close lasting fabrics. It is simply this: given a fibre which must be cut, torn, and minced and pounded into particles so minute that they cannot be distinguished except by a microscope; so minute that when boiled and mixed with water, they merely make it like milk or cream, so like butter-milk, indeed, that you could not tell the one from the other; yet, if that creamy fluid is poured out anywhere on a fine sieve or a flannel cloth, or some such surface, and pressed and dried, it will form a firm felted mass such as we can best describe by telling the reader to examine coarse blotting paper. One would think that any stuff that would thus make a pulp would make paper. For example, some juices make a pulp and turn out India-rubber and guttapercha. But paper pulp is quite different and its requirements special.

We come now to the consideration of certain substances that fulfil or partly fulfil these requirements. A number of them we are wholly unacquainted with, but there are some with which every one is more or less familiar. We have already set cotton aside as too valuable to be cultivated solely for paper. But flax deserves attention. In many parts of India the stem is wholly thrown aside as refuse, the seed alone being valued for making oil. A great industry seems possible in flax fibre, which at present is only used for string and rope. So also is *sunn* or tow, from which a good deal of native paper is made, but even that is often mixed for paper with a certain amount of cotton. The American aloe is counted a specially valuable fibre. When pains have been taken with it, it turns out first-rate, and is remarkable for the extraordinary strain it stands when made into rope. But at present no economical process has yet been invented to [illegible] the fibre from the refuse easily and cheaply. When this is done, it will attract more attention. The leaves of the wild date palm appear to be a very promising fibre. The palm grows in the most miserable sandy deserts and down the Indus Valley in great forests, only utilized by the natives for toddy making. As toddy-drawing spoils the fruit, but does not kill the leaves, there seems a hope that the licenses for toddy drawers may, some time or other, be printed on paper made from the leaves of the trees themselves.

Sugarcane refuse, which is now made into ropes for wells, &c., is also a substance that is now wasted in great profusion. In the United States, the home of economy and invention, the refuse is greatly made use of for the coarser kind of paper, and doubtless if we had local paper mills, we should also use up much of this for the same purpose.

From the above enumeration we have omitted all we did not think of much importance, and those also we thought of extra importance. One of the latter is the plantain. It cannot affect the Punjab much, so we may let it pass. The next is the bamboo. The bamboo grows freely in great forests all along the base of the hills. It already furnishes an important traffic, and it appears that its fibre is very valuable for paper. The Chinese have used it from time immemorial. It would scarcely pay to send home, but it grows just in the places where Indian paper mills would necessarily be started, that is about the clear streams of the lower hills, so that it is especially important to consider it always as a source of supply upon which a paper company could depend.

In the Government Report it seems to us that the river-side grasses have not received enough of attention. Perhaps it is our misfortune that we do not recognise the various *hibisci* under their scientific names, but if they were thought valuable, they would probably be better described. Yet the two most ancient papers in the world were swamp reeds—papyrus and rice. Moonj grass is barely mentioned, yet its fibre is incontestably very valuable. Rice straw is noted merely to be passed over. Wheat straw, which is here pounded up into bhoosa, if capable of making good useful paper. Wild bhung gives a very strong fibre and grows wild everywhere, especially in the hills; so common is it that its young leaves alone sell for about a rupee a maund as an intoxicating medium.

And lastly, we recur to a plant which we mentioned incidentally towards the beginning of our remarks. It is called in Punjabi *muddar*. Every one knows it. You have only to glance over the Anarkulli maidan to see it growing everywhere—a shrub about three or four feet high with thick greenish blue leaves and a thickish stem, generally considered an instrusive weed. As for the jungles, it grows everywhere over them and on the bare plains of Meean Meer just as it does at the back of your cook-

house, it is not particular. If you give it a flick with a whip, instantly milk springs out from the leaf. If that milk gets into your eye, it will blind you; if it is rubbed on your skin, it will raise a blister; if cows or sheep eat the plant, they will die; if goats eat it, it improves their digestion. If you collect the milk, it will form guttapercha, and can be worked in the same way and submitted to the same tests. It has, at the proper seasons, a large violet coloured flower which turns into a seed pod, which when it opens, displays a beautiful floss-silk down which the wind scatters everywhere. This down makes up into a beautiful fabric, but it has not been much experimented on. It makes, we may remark confidentially, a most beautiful stuffing for pillows, rezais, and cushions. But its chief importance is that it has been found to be a splendid fibre plant. It bleaches beautifully, it is very strong, and it turns out an economical paper even when gathered in the jungles here and sent to England. In short, to recapitulate, it produces "a first class fibre, tenacious, elastic, and lustrous; and a cotton silk-like, smooth and glossy; and a juice with some of the properties of gutta percha," and certain medicinal qualities which have only partially been investigated, and it grows profusely as a weed in the worst and most desolate soils and regions of the Punjab. Its scientific name is *calatropis gigantia*, or C. Hamiltonii.

The above remarks have all had reference to the export of fibre for the English mills. But why is so little done in India? Whatever is done must be done in the pleasant little lower hill valleys, the land of clear streams and bright foliage. But, as yet, no railways approach these districts, and until feeders are thrown out to the foot of the hills, we shall see no such enterprise flourish. Beer seems to flourish apparently, because people will drink beer when they hate the very sight or mention of paper. Sugar in the Punjab has as yet scarcely had a fair trial, but, combined with rum, will probably make its own way. Whisky distilleries have not started yet, all the Scotchmen hereabouts being busy as yet in less congenial but more urgent labors. Wool mills are in a similar state of dubious popularity. But we prophesy that the next company will be a paper mill, and would indicate the localities of Kalka, Hooshiarpore or Pathankote as very suitable places for such a venture.—*Civil and Military Gazette*.

SUGAR-CANE IN AUSTRALIA.

THE different varieties of sugar-cane removed from the Botanical Gardens in 1878, to a portion set apart for them in the Oxley Reserve, have thriven exceedingly well, and answer in every respect my most sanguine expectations. The whole appear to be in a thoroughly healthy state, many of the canes having joints from 8 inches to 9 inches in length. I had intended this season to have each variety tested as to sugar-producing capabilities, but, considering the comparatively recent removal, and finding some difficulty in forwarding the cane to the mill, I have decided to allow the test to stand over until next season. Specimens of the principal varieties will be exhibited in stools at the forthcoming exhibitions. During the past year I have received the following:—From Hawaii—*Saccharum officinarum*, var. *Manulele*, Striped Bourbon or Black Striped; from Singapore, Saigon, and China—*Blanches du Cap*, Gingau, Chinese, Annamite Vamboir, Coki, and Diard; making in all a most valuable addition of 78 new and different varieties, all of which are now under successful cultivation. Promise has also been received from H. Murton, Esq., Director of the Botanic Gardens, Singapore, of varieties of cane from Pondicherry, which will be most acceptable as an addition to those already in our possession. This gentleman has always evinced a most lively interest in the progress of the sugar industry in this colony, and it is to him specially, and others in the southern islands of the Pacific, I am indebted for the most valuable specimens of cane we possess. From the period of my first entering into the duties of these gardens in 1854, I have endeavoured to collect as many varieties of sugar-cane as possible, not only up to the time of its cultivation in the colony as a commercial industry, but up to the present, and by closely observing them during their growth, and noting their peculiarities as to climatic and other natural requirements, have invested the collection with an amount of interest which will, I am persuaded, prove to be of considerable value in the future. Both individual experience and correspondence prove that the use of one class of cane, continued for successive seasons and extending over many years, materially deteriorates the quality; and the substitution of new varieties, to ensure successful growth and productive qualities, becomes imperative.

The applications for cuttings have not only become very numerous, far exceeding those of previous years, but have arrived from various parts of the world where the growth of sugar is an established industry. Different varieties suitable to the climate have been forwarded by request to the West Indies, South Carolina, and other States of America, the Sandwich Islands, Hawaii, and the Mauritius (no less than two tons weight of cuttings having been sent to the latter place), all of which were supplied from the plantation at Oxley previously referred to. I am glad to be able to report, also, that the demands for cuttings from the various districts of Queensland, from their large extent, show in a marked degree the increasing popularity this important interest is gaining with our agriculturists. Rockhampton, has not hitherto been tried as a sugar-producing district, in a commercial point of view, although I have repeatedly called attention to it, as possessing a climate suitable for its cultivation. I am, however, glad to say that an experimental plantation is about being formed by a Mr. Hall, of Rockhampton, consisting of about fifty acres of selected ground, and I have arranged to supply him with sufficient cuttings (98,600) of suitable varieties to plant twenty acres of ground, in the hope that with proper skilful attention the venture may prove a success, and become the pioneer of more extensive operations conductive to the permanent establishment of the industry in the district. Instancing the large proportions to which sugar cultivation has attained in this colony in a comparatively few years, I find the following results, obtained from official sources, of the operations for the year ending December 31st, 1878:—

Areas under sugar-cane	16,584	acres.
Acres of sugar-cane crushed	11,005	"
Sugar produced	12,856	tons.
Raw sugar exported	3,380 $\frac{18}{20}$	"
Refined sugar exported	754	"

whilst the importations for the same period amounted to 250 tons of raw, and 54 tons of refined sugar. The quantity of molasses manufactured considerably exceeded half a million gallons, and the quantity of rum distilled, over 200,000 gallons—a vast and notable increase during the space of eleven years; the number of tons of sugar manufactured in 1858 being reported as 619. I am also credibly informed that the acreage under cultivation at the present season is considerably beyond that of last year, and the crushing has commenced under most favourable circumstances with every prospect of a most satisfactory yield.

The disease, or rust, which has made its appearance upon some of the plantations in this colony still occupies the attention of the growers and scientists, but, notwithstanding continual experiments both here and upon specimens specially sent to England for the microscopic examination of most eminent men, nothing definite or conclusive has yet been arrived at as to the actual cause of the disease, although the effect of it, so far as the rust is concerned, is generally conceded. Professor Liversedge, of the Sydney University, attributes the disease to *defective conditions of cultivation*, and I am still of my previously expressed opinion, which is corroborated by the majority of the planters with whom I have been in communication on the subject, that the true cause of the disease is the climatic changes to which some of the canes have been subjected, by being removed from their natural habitat, and being of too weak constitution to sustain the extraordinary claims upon their being placed under an uncongenial influence; and experience has shown that where diseased cane has been removed to a position where the temperature is assimilate with its original growth, the disease entirely disappears. I may also, with equal confidence, express my opinion that the disease is not contagious, for I have witnessed in plantations, where several varieties have been planted in close proximity to each other, some were to be found afflicted strongly with the disease, whilst others of a more robust nature in their immediate vicinity were entirely free from it. Another and most important question arising out of this vexed question is, how far the disease retards the growth of the cane or reduces the density of the juice? This is a matter not yet touched upon by those who have made this inquiry a speciality, but, so far as I can understand from those most interested, the damage is slight, if perceptible at all.—WALTER HILL, BRISBANE, in *Journal of Applied Science*.

SERVICES OF BIRDS IN AGRICULTURE.

PEOPLE often venture the statement that every object in Nature is of some use, directly or indirectly; but I fear if they were questioned as to the precise use and benefit we derive from certain members of the animal and vegetable kingdoms, they would find it rather difficult to prove the correctness of their assertion. Among the many natural enemies of the cultivator of the soil, slugs, snails, grubs under, and weeds on the surface, form a large and by no means contemptible part. That it were useless and unavailing for man himself to endeavour to exterminate these pests, is undeniable; and the only help he can expect must be from birds who, in their search after food, are unwittingly of immense use to him, some of them carrying destruction amongst the animal pests, and others against the vegetable ones. Some notes and facts on these services may not be out of place in this journal, and we will first take an insight into the way in which the former are kept under; of course the eventual extinction of these pests is not to be hoped for.

Amongst all our larger birds the *Corvidæ* or ravens are far and away the most aiding to the farmer, and of these the Starling shows to the fore in a useful aspect, its services being something, incredible; slugs, snails, worms, and beetles all form indiscriminate food for this most valuable bird. Statistics in such a case may seem odious, but I believe a German naturalist, with the extreme perseverance characteristic of his nation, once computed, and not incorrectly, that a single young Starl[illegible] snails in 14 hours out of the 24. Now, if we deduce further facts from this, we [illegible] see what a valuable aid to the cultivator the Starling is and how deserving of our protection. Nor is there, as far as I know, any set off against these good works; the Starling never attacks plants or grain of any kind, but will search with great diligence amongst new-sown wheat after noxious things, especially young slugs and worms.

Passing to our old and well-known friend the crow, we find that we are indebted to it also for services which, although rendered on behalf of itself, benefit us in no small degree. Not only grubs and their countless more or less distant relations fall victims to their accommodating and lasting hunger, but insects of all sorts and sizes, whose unwelcome pre-

sence is so detrimental to the soil on or in which they are, besides mice, which they destroy in great numbers and greedily devour.

The old discussion, whether the rook does more mischief than good, or *vice versa*, crops up continually from time to time, and the same old arguments are put forward by both sides to prove what is really a question more of locality and circumstance than a general one. Under certain conditions I consider the rook to be a nuisance, and under others a thing to be sought after, and therefore, without offering an opinion, I will state the facts of the case, and leave others to draw their conclusions. For the most part the food of the rook consists of cockchafers and their exceedingly destructive larvæ, besides slugs, worms, and grubs in lesser quantities: but it is also exceedingly partial to fruit, corn, and seeds of all kinds, not to mention young ducklings, chickens, young hares, rabbits, and game of all sorts. Then it must be allowed that the number of the former that they destroy is very considerable, especially the cockchafer larvæ, the liking for which they alone seem to have amongst birds.

Another exceedingly useful member of the *Corvidæ* is the jackdaw, but it is not nearly so plentiful as the crow and rook; consequently—for the same reason that white sheep eat more than black—they do not destroy so many hurtful insects as their less scarce relatives. Insects, snails, worms—in short the whole category of the animals, are devoured by the jackdaw, especially grubs in ploughed land. Mice also form a part of their food, and they eat a little corn as well, but not much; in fact, the loss could never be noticed.

One cannot help admiring the wonderful and surprising instinct of these three birds in discovering the whereabouts of the animals and insects on which they feed. They seem to be guided to the exact spot, and all they have to do is to thrust in their beak and draw out whatever may be the unlucky victim. It is curious that the ravens should include amongst their members really useful birds, thoroughly worth the farmer's protection, and birds so undeniably destructive as the magpie and jay, the former even more so than the latter. The mischievous and hurtful propensities of the magpie are only surpassed by its extreme daring while in search of its food. The first of these two birds eat a minimum of insects, and feed chiefly on fruit seeds, corn, in fact anything it can find to suit its by no means dainty palate; and does incredible harm in field and farm-yard. What is more the crow gets blamed for a great deal of the mischief the magpie perpetrates, I doubt if there is any, among all the birds we are proud to call British, whose mischievous propensities are so widespread.

Although the jay is not quite so unwelcome on farmed land as the magpie, still it is a bird whose room is always preferable to its company, for it is most impartial as to what it eats. Like the magpie, it will consume a few insects, but while it can get corn or seeds in plenty, coupled with an occasional duckling, or chicken, it will always prefer this comparatively easily collected food to the more scarce and less tasty and satisfying insects.—*Moorman, in L. S. Journal.*

THE CAWNPORE EXPERIMENTAL FARM.

THE experiments made in the Cawnpore Farm last year, as detailed in the report for the *rabi* season, 1879-80, seem to have been of a more practical kind than usual, and remind one of the doings at Sydapet in the Madras Presidency. The first series referred to in the report under notice are those made with different kinds of manuring. We are sorry to see that no attempt was made to introduce poudrette, which has, of late become so popular among the cultivators around Poona. The manures tried were—bone superphosphates, dissolved guano, and green manure consisting of a crop of indigo ploughed in. The table recording the result is so interesting that we make no excuse for transcribing a part of it:—

Manure applied per acre.	Outturn, grain.	Straw.	Total value.			Cost per acre.			Profit per acre.		
Mds.	lb.	lb.	Rs.	A.	P.	Rs.	A.	P.	Rs.	A.	P.
Bone Superphosphate, 2 mds.	1,627	2464	49	10	8	27	12	9	21	13	6
Ditto, 3½ mds. ...	1,894	2,927	59	0	11	31	4	5	26	12	0
Dissolved Guano, 1½ mds. ...	1,427	2,196	43	11	2	34	6	5	9	4	6
Ditto, 2 mds. ...	1,778	2,881	55	0	8	39	9	7	15	7	1
Indigo crop ploughed in ...	1,430	2,994	47	0	8	30	8	3	16	8	0
No manure	1,171	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	3	15	8	4

It will be observed here that guano stands low in the matter of profit. This was brought about by the great cost of laying the guano down at Cawnpore, amounting to Rs. 9-14-8 per maund equal to Rs. 270 per ton, a price which practically placed it out of the competition. The bone superphosphate, obtained by crushing bones, and treating them with sulphuric acid and hot water, furnished a manure, which cost Rs. 8-7-8 per maund, and could, in fact, be made much cheaper were it not for the very high cost of, and frieght on, sulphuric asid. This solvent stands the cultivator in 8 annas per lbs. at Cawnpore. Three-and-a-half maunds per acre raised the produce from 19·5 bushels—the outturn of the standard and unmanured plot—to 27·1 bushels per acre. It must be remembered that the whole of this soil, having been more or less under experimental treatment during the past three or four years, was in better condition than the ordinary soil of the country, hence the high outturn of 19½ bushels per acre. We should mention that wheat was the crop experimented with Mr. F. N. Wright speaks of this rather as "a full average outturn for good lands, under the native system of cultivation." We must point out here that the general average all over India is 14 bushels, therefore 19½ is a high outturn, and 27 a striking illustration of what high cultivation can do. The cost of each experiment is very carefully debited—a matter not always attended to in these experiments. For instance, the land being on a Government farm, it is customary to ignore rent. This is unfair, and in this series of experiments, the cost has been made up as follows:—

	Rs.	A.	P.
Rent	6	4	0
Irrigation	3	12	0
Cultivation	8	8	8
Total, Rs.	18	8	8

The rent is based on the average rent of 12 fields adjoining the farm, and the outturn is valued at the rates current at Cawnpore when the grain was ready for the market. The experiments, therefore, have a value not always to be found in such trials, and they are conclusive as to the benefits of manuring. When will the ryot understand that he has just the same rent revenue, and canal dues to pay whether his crop is 14 or 27 bushels per acre; or, in other words, whether his profit is Rs 10 or Rs. 26, per acre per crop? It is worthy of note, too, that the amount of straw—the value of which was included in the above tabulated figures—was very much increased in amount, and when farmers use this for cattle-feeding, it must be of great value to them. The increase on the plot, with 3½ maunds bone manure, was 75½ per cent. Not the least interesting feature in this series of experiments is the result obtained from the so-called unmanured plot. It is true that no manure was applied with the crop, but in 1877-78, a mixture of blood and bones, to the extent of 5 maunds per acre, was applied, and it is well known that the effects of bone manure are lasting, as was clearly shown in this plot producing 19½ bushels per acre, which is 39 per cent. above the average of India. A second series of experiments was tried, in order to find the effect of carefully selecting seeds, instead of taking it at random from the *bunnia*. The result was a wheat crop of 23¼ bushels per acre from the selected seed plot against 18½ from the other. The respective merits of thin and thick sowing were tested, and resulted in favor of close sowing.

We do not, however, consider the experiment to have been at all a fair one, as the amount of seed, used for thin sowing, was ridiculously small, being only 16lbs. per acre, as against 110lbs. This, we consider, to have been too extreme a test. Two plots were alike treated to 50 maunds farmyard manure, and in every other respect, except irrigation, they were treated in the same manner. The unwatered plot yielded 17 bushels grain, and 24 maunds straw, while the irrigated plot gave a return of 30½ bushels grain and 41 maunds straw, the extra cost of watering having only amounted to Rs. 3-12. Some experiments were made in the way of introducing wheat and barley from England, America, and Australia; and the general conclusion arrived at seemed to be in favor of improving the indigenous variety by careful selection. This, we believe, to be a thoroughly sound decision. Dr. Forbes Watson has told us that, in many districts in India the finest wheat in the world is grown; and there does not seem any reason why we should not indent on those districts for seed wheat to replace the more common varieties of other places. The Indian ryot has been for centuries engaged in cultivating the same grain on the same fields, and deterioration has invariably been the result of such a course all the word over.—*I. D. News.*

CITY REFUSE AS MANURE.

THE importance of having an adequate supply of manures in this country cannot be exaggerated. Mr. James Caird, the great authority in such matters, has, by carefully conducted experiments, proved to demonstration that the difference between the best and inferior agriculture on the same *soil* may be more than treble the produce. Wheat grown without manure yielded 730lbs., and wheat grown with special manure yielded 2,342lbs. The great difficulty in the way of the introduction of improved methods of tillage in India is the want of a sufficient supply of manures. The Indian cultivator must afford to manure his fields properly, and that is the main reason why the soil is becoming gradually exhausted. Such being the case, a peculiar interest attaches to the experiments now being made at Poona to utilise city refuse as manure. The use of poudrette as manure was unknown in the Bombay Presidency until recently; but the Poona Municipality has now been realising a considerable revenue from the sale of poudrette since the opening of the Mutha Canals. Some information about the manufacture and sale of poudrette in Poona will no doubt interest the reader. The population of the city is 90,436 souls. About forty-four cartloads of night-soil, equal to 575 cubic feet, are collected daily, and carted out to a depôt at the village of Dhanpodi, two and-a-half miles off from the extreme limits of the city. Then there are the street and house sweepings collected from the dust bins of the city. They amount to sixty-five to seventy-five cartloads, equal to 1,950 cubic feet, per day. These are carted out; and when burnt and sifted, the produce is 300 cubic feet of ashes. The process adopted in the preparation of the night-soil of

the city of Poona into poudrette is what is called the sun-drying process. The 575 cubic feet of night-soil shrinks in drying to 430 cubic feet of night-soil. Mixed with 300 cubic feet of ashes the produce is 730 cubic feet poudrette per day, or 226,450 cubic feet per annum. Experience has shown that to ensure thorough deodorisation, complete freedom from stink, and the best poudrette, the proportion of ashes to night-soil should be about equal; but as this is not now the case, the supply of night-soil being 430 cubic feet, and that of ashes 300 cubic feet per day —the Municipality are now trying to augment their collection of ashes to the required amount. The price realised is one rupee per cubic yard, or 27 cubic feet. The annual value of the poudrette prepared and sold by the Poona Municipality is Rs 9,870. The revenue realized by the Municipality from this source has been steadily increased. It has risen in five years from Rs. 766 to nearly Rs. 10,000. The cost of conveying night-soil and sweepings to the depôt comes up to Rs. 11,736; but as this cost has to be incurred in any case, it need not be taken into account. The manufacture of the poudrette costs Rs. 6,264. The annual revenue from the 266,450 cubic feet of poudrette prepared by the Poona Municipality is almost Rs. 5,000. The Secretary to the Municipality thinks that this revenue is susceptible of considerable development. The expenditure for removing the refuse of the city and the cost of preparing it into poudrette can be reduced by Rs. 3,000, while the sale proceeds of the manufactured article can be raised to Rs. 7,500 by increasing the price of the manure. The Secretary to the Poona Municipal Committee makes the following remarks on the value of the manure prepared by the Municipality :—"The manure prepared in this manner is much valued by cultivators, and is in great demand. Applications for the manure have been increasing since the opening of the Mutha Canals, and consequent extension of wet cultivation. Five years ago agriculturists would not touch the poudrette then prepared, and could not be induced to take away at even a nominal charge. At the present moment the outturn of manure is not enough to keep pace with the demand, and it has become necessary to take special precautions that the poudrette is not taken away in its raw state which the cultivators sometimes attempt to do. They frequently pay for manure from four to six months *in advance*, in order to ensure a timely supply. The poudrette manufactured by the Municipality is clean and free from brickbats, broken glass, and other rubbish or common earth. This is secured by the ashes being sifted before being mixed with the night-soil." Those who are never tired of speaking of the prejudices of native cultivators as an insuperable obstacle in the way of agricultural reform in India, should carefully note the facts recorded by Mr. Narso Ramchunder, Secretary to the Municipal Committee of Poona. That the cultivators did not touch the poudrette, when it was first prepared five years ago, was no more than what could have been expected. But as soon as they found that the use of the manure would prove remunerative, their prejudices at once vanished into thin air. They are now so anxious to have a supply of the manure that at the present moment the outturn of the article is not enough to keep pace with the demand, and that cultivators frequently pay for manure to the Municipality in advance, in order to ensure a timely supply. A fact like this is enough to overcome a thousand speculations. Show the Indian cultivator that he will be a gainer by the introduction of any new method, and he will be at once found ready to adopt it. It may be supposed that the manufacture of the refuse of the city of Poona into poudrette is carried on in such a way as may prove injurious to the public health. But we are glad to see that there is no ground for such a supposition. The Sanitary Commissioner of the Presidency has placed on record his opinion that the management of the depôt reflects the highest credit on all concerned. "I have," he says, "visited it often and unexpectedly, and remembering how rude are the means as they generally are in India, I can answer for it that every process is very carefully conducted." The example set by the Poona Municipality should induce other Municipalities in India to utilize the sewage of their town. —*Deccan Herald.*

CACAO PLANTING.

THE cultivation of cacao in this island has for some time past assumed proportions which promise to render it, at no distant date, a very important feature of our local industries and the increasing favor in which the article is held at home, added to the decline in its cultivation in other countries, seems to indicate a steady demand for it at remunerative prices.

There is no published account of the mode of cultivating the tree, and preparing the product, and the letters from the father of Ceylon planters on this subject, did not convey much that was new or of a practical character. There are accounts of the article by Simonds and other writers, but these are of a very general nature and chiefly statistical, and of little practical value therefore to the planter. We think it may be useful to many of our readers if we place before them our own experience, and such information as we have gathered on the subject.

To begin at the beginning, we may say to the cacao planter, choose well-sheltered land with a deep soil as cacoa is deep rooter : the more loamy the soil is the better, rocky or stony land should be avoided. As to shade we believe that it *is* necessary, and we cannot think of a better shade tree than the *Inga Saman*, which grows rapidly, and casts during the day a checkered acacia-like shade, and closes at night so as not to intercept the dew : until the trees are large enough to give shade, we should recommend the annual planting of castor-oil plants, which will grow to a height of 15 feet in six months, so that during the hot season the young cacao could be overshadowed by it, and at the return of the cool season, the castor oil tree be bodily cut down, and returned to the soil ; if this method is adopted, the plants must be vigilantly watched, as a most destructive caterpillar sooner or late developes upon the castor oil plant, when it must at once be cut down, but as this pest never attacks very young trees, it is not a material difficulty. Another common plan is to clear the land, and quincunx the cacao with Liberian coffee, that is to say the cacao is planted 15 × 15 with a Liberian tree in the square : this no doubt adds quickly to the value of the clearing, but our opinion is that shade-grown clearing of cacao alone is in all respects more satisfactory, and in the end, more profitable. As regards the distance of the plants apart, it, in a measure, may depend upon the variety selected, and the altitude of the land, but supposing a rich low-lying flat be obtained, and Caraccas cacao be the kind selected, we think 12 × 12 as close as the clearing should be planted. On one fine cacao estate, near Kurunegalla, the proprietor has planted 9 × 9, with the idea of taking out alternate diagonal lines in about five years, after which the remaining trees will be in squares 18 × 18, with a centre tree to each square (or 13 4 × 13 4); in consideration of the value of seed-pods in Ceylon, this may prove to be good policy. It is considered a mistake unless in an exceptionally wet season, to plant *in situ* ; the safest method is to put out young *plants*, under shade, in clay pots (the pots are merely long and narrow cylinders) ; while the young plants are growing in the pots, great care must be observed to keep them from the effects of damp, too much shade, and the attacks of insects, up to a certain stage the Cacao plant is extremely delicate, but once past this it may be considered a hardy tree. We have said that we think 12 × 12 to be the proper distance apart for planting ; this will allow three hundred plants to the acre, the approximate cost of opening an acre may be estimated thus :—

Plants	...	...	... Rs.	25	0
Felling and burning		...	... „	15	0
Lining	...	...	... „	1	50
Holing 2 × 2	...	...	... „	6	0
Filling in	...	...	... „	4	0
Planting	...	...	... „	3	50
			Rs.	55	0

The growth of the plant, once having well started, is remarkable ; plants put out at two months old, have grown to a height of four and five feet in the year. It will be necessary at about seven to eight months carefully to remove all suckers ; regarding pruning, Simond's model is a "straight single stem up to three feet from the ground, and dividing into two or three as it grows higher : each of these again, divided into two or three branches make up the framework or principal branches which terminate numerously in the leafy branches, regularly disposed into a well-formed head ;" practically this means that all matted and weak branchlets are to be removed as well as lateral branches growing at *right angles* to the stem, and a "chick-like" growth encouraged. Should the young trees as, often happens, lean to one side the top should be nipped off, and it will ultimately recover its shape again. The cacao tree, though it will bear at two years, is not fully matured until its seventh or eighth year, and the probability is that pods on trees younger than this contain immature and consequently unreliable seed. A gentleman on whom we place reliances, lately told us that in the London market it is said that we have not yet sent home the higher class of cacao, and we certainly think that more care should have been displayed in its selection. The Venezeula, or Caracca, Cacao, is the best, although it, according to Simonds, has deteriorated in Trinidad. The pods of this tree are small, but the seeds are more luscious, and globular in form, while the price is very much higher than the common West Indian variety, and we strongly advise intending cacao planters to take care to obtain this seed, especially as we consider that the Caraccas tree will soon become acclimatised here. We confidently prophecy a great future for cacao in Ceylon, and shall be glad fully to ventilate the subject of its cultivation in our columns : experience will no doubt teach us many things not now understood, and it will be well that the results of observation be brought together for the general good. —*Ceylon Times.*

VEGETABLE IVORY.

AS a substitute for ivory, in the manufacture of certain small articles such as buttons, rings, umbrella handles, &c., where hardness is not so much a desideratum as a fine white color, the use of the so-called "vegetable ivory" is largely increasing, and the trade in the nuts producing the material is becoming very extensive. The vegetable ivory nut is the produce of a species of palm which is met with in a wild state in South America and Africa. When imported into Europe the nut somewhat resembles a Brazil nut, only it is circular in shape, instead of triangular ; and they are about the size of a large walnut or small orange. Inside the hard shell is the hard, white "kernel," resembling ivory in appearance. This solid matter, being softer than ivory, and easily carved, or turned in the lathe, and being easily dyed, and less brittle than bone, is largely employed in the manufacture of buttons and similar articles. When exposed for length of time to the air it assumes the granular appearance and the rich yellow, or rather creamy, tint of old ivory. This hard "kernel" is, in its natural formation, of the same nature as the kernel of the cocoanut. The unripe fruit consists of green shell, containing a watery fluid, which, as the nut matures, [illegible] becomes a pulpy mass, and eventually hardens into solid matter. The [illegible] though bitter to the taste is wholesome, and often renders invaluable service to travellers who cannot otherwise obtain water to drink. It becomes sweeter as it thickens, and in South America the pulpy mass is mixed with sugar and water, and largely consumed as a favourite beverage. The tree on which the fruit grows is unlike an ordinary palm, having little or no stem, and drooping downwards, especially when the weak branches are overweighted by the six or seven bunches of nuts—each bunch containing six or seven seeds enclosed in their thick and heavy shells and outer sheath, and weighing altogether from 20 to 24 lbs. Birmingham alone often uses as much as a ton weight in a day, of these nuts, and the annual import into this country (England) amounts to a value of at least £100,000, while equally large quantities are used in France and in other parts of the Continent.—*Hatters' Gazette.*

PAPER FROM BAMBOOS.

THE attention of Forest Officers in Burmah has lately been turned to the possibility of making paper from bamboos. Experiments were made last summer in Claxheugh, near Sunderland, with bamboos sent from Burmah, and the result, it is officially reported, "was an exceedingly strong and even paper, marred only by numerous yellow, scabby looking spots, which, under a magnifying glass, it was easy to see were pieces of hard silicate, the outermost skin of the bamboo, which had not been sufficiently affected by the boiling in the alkali solution." By a more effectual treatment in the caustic solution, it is conceived that these glassy scales would be destroyed; but in any case, if bamboo shoots are used while they are still young enough, there is no glassy skin to be afraid of. Well then, it will be said, cut the shoots young enough, and the difficulty is overcome; but this is not so. After they are cut, they soon harden on the surface. To use them for paper making successfully, it is necessary to work them up while they are still freshly cut, and the inference from this, it will be seen, is that the manufacture can only be successfully carried out in the country where the bamboos are grown. The production of bamboo paper, in fact, is pointed out by Providence as a Burmese industry. The Pegu conservator, who has been employed by the Government to report on this subject, has made some interesting calculations as to the prospects of the undertaking. In order that a factory may be profitably worked, he says it is necessary that it should turn out 3,000 tons of stock annually. Now it would take 1,000 large green bamboos to yield one ton, or 3,000,000 shoots for each factory. A good bamboo forest can yield 150 young shoots per acre, and would therefore consume the outturn of nearly 32 square miles. But bamboo forests of this extent are available in many parts of the Pegu circle. Obviously it would not answer to depend permanently on the wild growth of Nature, but persons interested are clearly of opinion that it would answer to irrigate bamboo plantations with the view of producing a perennial supply of young shoots, and that meantime a factory could be profitably established at Pegu.—*Pioneer.*

THE PRODUCTION OF SUGAR.

THE production of sugar from the "Imphee" of Africa has engaged attention for some years past in several tropical countries. As closely allied to our "Jowar" or "Janera," it has naturally attracted notice in India, and under the name of *sorghum saccharatum*, its cultivation has been attempted in various districts, but, we believe, unsuccessfully as a sugar yielder. The idea of obtaining sugar from this plant and from maize, in sufficient quantity, or good enough, for public consumption, has been ridiculed by many, more especially in the West Indies. But our indefatigable trans-Atlantic brethren have nevertheless been persevering in their endeavors for some time past, and success is now crowning their efforts. The Indians, too, have taken kindly to the culture and to the extraction of the sugar. The result of trials, so far, has led to the conclusion that sugar of a first-rate quality is obtainable, and that it compares favourably with the best product from sugar-cane grown in the most favourable localities. The cultivation has, it appears, been tried far down in Texas and high up in Minnesota; and that plant has everywhere been successfully raised, and has proved prolific. One great point claimed in its favour is that its saccharine matter is entirely derived from the atmosphere, so that, even though cultivated year after year, there is no reason why it should not increase in fertility. This seems rather doubtful, but those who make the assertion have, they say, good authority for it. The crop of seed is very important for breadstuff. Moreover, good vinegar is obtainable from sorghum skimmings and refuse. The best manures are phoshates, lime, wood ashes and plaster of Paris. An important authority, Professor Caldwell, of Cornell University, is in favour of beet sugar production, and thinks that sorghum stands little chance in competition with beet; but he agrees that there is one advantage in its favor, in the fact that it requires less machinery and less capital. In other words, "sugar can be obtained from the cane, in a small way, for home consumption better than from the beet." Be this as it may, this new industry is regarded as of the greatest importance to the country.—*Englishman.*

THE IMPROVEMENT OF THE POTATO.

WHILE commending the action of Government in its endeavour to introduce a good description of potato in these hills, and thanking Lieutenant-Governor for the liberal grant of money which he has made for the purpose, we would strongly deprecate any importation of potato seed from America. The desire is, we believe, to try various seeds with a view to ascertain and establish those descriptions that give the best results, and with this object seed will be imported from England, Australia, and probably America. We have nothing to say against importing from the two first countries, but we would warn those concerned against having anything to do with seed from America, as it is almost certain to be accompanied by that dreadful pest the Colorado beetle. The ravages of this prolific and almost indestructible insect have been fearful in America. At one time this beetle was an object of great dread on the other side of the Atlantic where the most careful measures were, and are still, taken to prevent its introduction. Nearly every mode of destroying it has been tried with very doubtful success, as the pest is still spreading. We read the other day that Colorado beetles have late been making themselves unpleasantly conspicuous by their proceedings in Westchester country, New York, where they have appeared in alarming numbers. The farmers and gardeners have pressed all their households and all the additional help they can muster into service to make war upon the pest in the potato fields; but it seems likely that in the end victory will rest with the Colorado beetles. The great specific is Paris green; but it requires such frequent application, and is, moreover, so dangerous to use where there are domestic animals that many farmers hesitate to resort to it, and prefer destroying the bugs by means of boiling water. Boys and girls and many other assistants are paid three cents a quart for picking bugs. One smart boy will pick from 15 to 20 quarts of bugs a day. The potato bug is, however, a cunning insect, or it thinks it is. It knows instantly when the vine is assailed, and drops on its back as though it were dead. When the intruder has passed on, it climbs up the stalk, and begins to feed on the leaves again. The effect of Paris green is most instantaneous. The bug drops rolls on its back, gives a few spasmodic kicks, and is dead. Whether it suffers much under these circumstances is a matter of doubt. The farmers generally hope it does but some of them are inclined to think that it does not.—*Darjeeling News.*

THE INDIAN WHEAT TRADE.

THE Indian wheat is a splended grain second to none, full of glutinous qualities which causes it to be in great demand, not only in England but also in France and Italy. It is grown most extensively in all that tract of country by the Nerbudda, spreading in the valleys to Cawnpore in the north, and the Raipore districts in the south, Jubbulpore being as near as possible the centre of the grain districts. The cultivation extends over hundreds of square miles, and although we are accustomed to read of the marvellous crops the virgin soil of the Western States of America and Canada will produce, yet here in India under our very eyes it is grown at a minimum cost, to which no other country can bear comparison. The almost nude native, with a pair of bullocks, and two rough pieces of timber made into a plough, constitute the sole farming stock, and a favourable monsoon the only fertilizer. With these advantages Indian wheat ought to be the largest item of export. The G. I. P. Railway runs through the heart of the wheat country from Sohagpore to Jubbulpore and Nagpore, is in direct through traffic with the East Indian Railway to Cawnpore; the distance is less from Jubbulpore to Bombay than to Calcutta by 168 miles. Yet it is cheaper to send it to Calcutta. The charges are as follows:—

			as	p.	
Nagpore to Bombay,	520	miles ...	11	9	per cental.
Jubbulpore to Bombay,	616	" ...	12	8	"
Jubbulpore to Calcutta,	784	" ...	10	3	"
Cawnpore to Calcutta,	684	" ...	11	0	"

This shows clearly how excessive the G. I. P. Railway chareges are, and although the old excuse will doubtless be urged, of the extra expense this railway incurs through having to traverse the Ghât, yet add 40 miles more to the distances of Nagpore and Jubbulpore for the extra expense of the ghât traffic, and it will still be seen the G. I. P. Railway rates are far in excess of the East Indian. Wheat is an article which has to enter into keen competition with other countries, and the slightest addition to railway charges takes away the small margin of the trader's profit. Our railways charge as much for a distance of a few hundred miles as the Americans do for thousands. For easy reference we quote at par exchange:—

Jubbulpore to Bombay ...	... 1*s.* 7*d.*	per cental.
Chicago to Liverpool ...	... 1*s.* 3½*d.*	"

With the splendid facilities of a new Prince's Dock and warehouses our grain trade ought to multiply tenfold, if the zeal which is exhibited in the United States were only imitated in India. It is a matter our Chamber of Commerce ought to take up warmly, for the interests of the Port Trust, and the port and trade of Bombay are most deeply concerned in seeing that the main trunk railway puts forth every energy to foster the wheat trade, instead of charging a prohibitive tariff, and if the object was to check and suppress it.—*Bombay Gazette.*

TREE PLANTING.

THE question of replanting many portions of tropical countries which have become denuded of forest trees, is one which is being taken up in India, and acted upon by the authorities. In the Madras Presidency, in some districts, the collectors call upon the cultivators to plant a certain number of trees during each rainy season, and the question has been seriously taken up, whether it may not be desirable to plant large districts of waste lands, and the roadsides with useful fruit-bearing trees, so that in seasons of food scarcity, if not in times of famine, the people may obtain relief from the produce of the trees. In some districts forest planting or renewing, is taking place in order to maintain the supply of firewood for the railways, in others, to ensure a supply of useful building timber which in many parts of India is becoming scarce.

In Ceylon, apart from the question of timber supply or effect upon the rainfall, there is the other question in reference to fruit bearing trees viewed either as producers of food for the people, or as a means of improving the public health, where, strange as it may appear, vegetable food is often very scarce; it is an admitted fact that in our towns and chief centres of population the supply of vegetable food is out of all proportion to the number of the inhabitants, and in a tropical country this is particularly to be deplored, as there can be no doubt that the absence of vegetable diet exercises a prejudicial influence on the health of the people.

It should be the effort of our Government to encourage, by all means in its power, the planting out of fruit-bearing trees by the

people, a course which could easily be adopted through the agency of the village Councils ; the same rural organisation which takes account of the repairs of fences and ellas might readily be called upon to see to the planting and keeping in order of a certain number of jack, breadfruit, and other trees, the produce of which would be at the disposal of the population. As we have advocated the propagating and the distribution of useful economic plants by Government authorities, so we would wish to see a distribution of fruit trees through similar agency. This has been attempted in one or two districts, but unfortunately the climate of those localities were ill-suited to the growth of young plants, but there can be no reason why in a large number of districts the rearing and distribution of useful friut trees should not be a most complete success.—*Ceylon Times.*

MANGABEIRA RUBBER.

THE largest quantity and the best quality of rubber has hitherto been imported from the Province of Para, Brazil, and although it has long been known that other provinces of that vast empire contained forests of rubber-yielding trees, these have never been taken advantage of, owing to the ignorance or supineness of the natives. The inhabitants of the province of Hernambuco are now beginning to realise the vast stores of undeveloped wealth existing in their virgin forests, and rubber is being exported from that province, which may, soon rival Para in the extent of its exports of this article. This action is almost entirely due to the exertions of Sanhor Joao Fernandez Lopes, who has spared neither time nor money in his endeavours to improve the agriculture of the province, and to develop its vast stores of natural wealth. This gentleman has issued a circular (dated April 26th, 1880) calling attention to this important source of wealth, and giving practical instructions for the collection and preparation of the rubber, from which the following is extracted :—

"Mangabeira rubber is the most suitable for the springs of railway wagons, tramway cars, and different machines, and for an infinity of other purposes. The process of extracting the milk from the Mangabeira tree is very simple and easy. Each person must be provided with fifty or more small tin basins and a small axe. He should make eight oblique cuts, sloping downwards at a little distance from each other, all round the trunk of the Mangabeira, cutting only the bark, and placing immediately below each cut one of the basins, securing these either with adhesive clay or nails. These small basins will collect the milk that exudes from the cuts, and when full, they must be emptied into a larger vessel. This process should be continued during the whole day, and thus three or four bottles of milk may be collected, according to the fertility of the trees. The cuts should not be deep, as the milk is secreted just below the outside bark ; and a great number of incisions should not be made on each tree, as these may weaken or kill the trees, which has been the case, in some instances with the seringueira, the tree from which the Para rubber is obtained.

"The Para rubber is made in the place where the milk is collected because, in the process of preparation by smoking, there is not time for the milk to be carried to the houses of the collectors ; but here we do not prepare the rubber as they do in Para, but make use of the process introduced into the province of Para, in 1860, by Senhor Strauss, which being much simpler, gives admirable results.

"The process is as follows :—Put a little powdered alum into a teacup full of water, mixing it well, then put a few spoonsful of this solution into a vessel in which three bottles of the milk have been placed, properly strained, to clear it from any extraneous matter. Immediately the milk coagulates, which will be in two or three minutes, the rubber must be exposed to the air on sticks and allowed to drain for eight days. After thirty days, it is ready to send to market in cases or barrels. We have tens of leagues of Mangabeira trees, and long ago we might have made use of this wealth, according to the opinion of Senhor Joaquino d'Almeida Pinto, an intelligent botanist of this province. The seringueira planted here grows perfectly, and there is no lack of different milk-giving trees that might be made useful. The province of Para exported last year three million kilogrammes of rubber, valued at six thousand coubos (£600,000.)—*Journal of the Society of Arts.*

THE PAPAYA.

A CORRESPONDENT supplies a Batavia paper with the following particulars of the properties of papaya juice :—

"I have again met with something new about the papaya tree. A short time ago, I reported that in the West Indies, meat is wrapped in papaya leaves to make it tender. Now I see that Frenchmen, on examining the white milky fluid present in the stem, stem fruit and leaves of the papaya, has found that this sap works like *pepsine.* Albuminous substances are consumed by it. It also attacks living tissues, so that the experimenter has tried it on living animals. He has thereupon injected it into hardened swellings which caused great pain accompanied by fever, but very soon made the hard swellings soft after which they were cut into and cure followed. Into a mixture of 4 parts water and 1 part papaya sap he also put a frog, of which after two days, nothing but the skeleton remained. All the flesh had been digested in the bottle just as it would have been in a stomach. After all this it is surprising that now that people know of so many plants which feed on flesh [that of insects, &c.], the papaya which possesses such a flesh consuming sap has no means of catching those insects it might so well feed upon."

OPIUM REVENUE.

Opium Revenue to date compared with the estimate for the year 1880-81.

THE following is the result of five sales of Bengal Opium and 4 months' pass duty on Opium exported from Bombay:—

PRESIDENCY.	Estimate.	Actual.	Better than estimate.	Worse than estimate.
	Rs.	Rs.	Rs.	Rs.
Bengal ...	2,52,62,500	3,19,77,995	67,15,495	...
Bombay ...	1,07,53,000	55,07,625	...	52,45,375
Total Rs. ...	3,60,15,500	3,74,85,620	14,70,120	...

CALCUTTA BOTANICAL GARDEN.

THE Annual Report of the Royal Botanical Garden, Calcutta, for 1879-80, was read on the 21st ultimo, and the resolution passed thereon was as follows :—

The work of remodelling the garden made considerable progress during the year. Additions were made to the ornamental water ; land was levelled and raised ; avenues were opened out and connected with the main roads ; and swampy ground was reclaimed and prepared for planting. The avenue of *Albizzia Paludosa*, which was laid out some years ago, promises to become one of the principal ornaments of the garden. Dr. King hopes to complete the laying out of the garden in two years more. It will then be possible to devote more minute attention to neatness and general maintenance.

2. Experience appears to have shown that *Rhcea* cannot be produced in Lower Bengal as cheaply or as plentifully as was supposed. The plant makes little progress in the cold season, and the stems produced at that period of the year are short and woody. To secure even a moderate yield of well-sized stems deep-hoeing, manuring and irrigation are necessary, and it is only on good land and at a considerable outlay that three cuttings in the year can be looked for. At present the practical importance of this inquiry depends in a great measure upon the result of the attempts to produce an efficient machine for cleaning the fibre.

3. The results of the trial in England of certain coarse grasses of Orissa, to test their suitability for paper-making, are not discouraging. It seems that the two varieties known as *Ranikharia* and *Tiansi* are little inferior to *Esparto* grass, which is so largely exported from Spain for this purpose. The *Sara* grass also appears to be of good quality. Dr. King's correspondent states, regarding *Ranikharia* and *Tiansi*, that "if they can be had in large quantities and at the price of *Esparto*, they might be worth trying on a large scale." Larger quantities will be sent to England for further trial at the close of the present rainy season, and the Lieutenant-Governor requests that the result may be specially reported as soon as it is known. Dr. King explains satisfactorily his failure to examine the long grasses on the banks of the Adjye and Damuda, rivers. The Lieutenant-Governor trusts that this work will be taken up during the ensuing cold season.

4. Among the economic plants of which trials have been made in the garden, the *Carob*, the *Eucalypti*, the *Pará* rubber, and the fodder-tree *Symphytum Peregrinum* must now be pronounced failures, and the Lieutenant-Governor sees no advantage in further attempts to induce them to grow in an uncongenial soil and climate. The *Ceará* rubber, on the other hand, promises very well. It is extremely hardy and is readily propagated. The Lieutenant-Governor hopes that it may be possible to tap the trees and test the produce during the current season. Dr. King anticipates that indigo and tea planters in the plains will find it to their advantage to cultivate this valuable and hardy tree. He has made a *Ceará* plantation " in expectation of large demands for young plants and seeds." Dr King makes the following observations regarding the Guango or Rain-tree (*Pithecolobium Saman*) :—"This wonderful tree grows faster than any hitherto introduced into Bengal, with the single exception of the *casuarina.* It gives a beautiful shade and yields a pod with a sweet pulp, which is greedily eaten by cattle. For avenues, cantonments, squares, and situations where dense shade is wanted, no tree is more suitable than this" The Lieutenant-Governor has already directed the attention of the District Road authorities to the advantage of planting fruit-bearing trees along the sides of the roads, and thus increasing the resources of the district, while promoting the comfort of travellers. The Rain-tree appears to be well adapted for this purpose, and also for the formation of fuel reserves near stations.

5. Altogether 46 Wardian cases of plants were received from different parts of [illegible] despatched, against 21 and 21 respectively in the previous year. Dr. King justly points to this increase as evidence of the growing usefulness of the garden in the distribution of exotics. The number of plants sent out in open boxes and pots was 19,447, and of plants so received, 6,055 in 1878-79. In the interchange of seeds there was a large increase, 6,457 packets having been distributed, against 3,972 in the previous year, and 2,448 received, against 1,307. There were also considerable additions to the herbarium, Among the chief donors of plants and seeds were Mr. Bull of Chelsea, M. LeBœuf of Argenteuil, Messrs. Haage and Smidt of Erfurt, and Mr. Van Houtte of Ghent. Those who made the most valuable contributions to the herbarium were Mr. Brandis, Inspector-General of Forests, Mr. Sykes Gamble, Conservator of Forests. Mr. Duthie, Superintendent of the Botanical Garden at Saharunpore, Mr. Fisher of the Assam Forest Department, Mr. Ford of the Hong-Kong Botanical Garden, Major Collett, M. Godefroy Le Bœuf, Archdeacon Hose, and Mr. H. O. Forbes.

Dr. King himself was able to add his own collection made during his visit to the Straits and Java. To all these gentlemen the thanks of Government are due.

6 The garden sustained a serious loss during the year by the death of Mr. Biermann, an officer of much experience and worth. Dr. King also refers to the departure of Mr. John Scott on sick furlough, and the Lieutenant-Governor has, since the submission of this report, heard with regret of Mr. Scott's death in Europe. Mr. Scott had been connected with the garden for seventeen years, and had held charge of the herbarium for a considerable period.

7. The progress of the *Lloyd Botanical Garden*, during the year reflects much credit on the Curator, Mr. Jaffery; several thousands of seedlings were raised and considerable quantities of plants and seeds were received and distributed.

8. The Lieutenant-Governor again tenders his acknowledgments to Dr. King for the thorough efficiency displayed by him in the management of the garden.

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The usual Monthly General Meeting was held on Thursday, the 22nd July 1880.

W. H. Cogswell, Esq., v. p., *in the Chair.*

The proceedings of the last Meeting were read and confirmed.

The following were elected members :—

Mrs. J. G. Macdonald, Messrs A. Springer, W. F. Swan, James Murray, and Rajah Rajendro Narayan Roy.

The names of the following were submitted for Membership :—

Secretary, Patna Municipality,—proposed by Mr. R. Bignell, seconded by the Secretary.

W. Mackenzie, Esq., Huttowrie, Belaspore, Tirhoot,—proposed by Mr. G. Toomy, seconded by Mr. G. Swaine.

Mrs. A. J. Hughes, Mozufferpore,—proposed by Mr. H. Stanley Collier, seconded by the Secretary.

Newton E. Jennings, Esq., Engineer, Kimedi Estate,—proposed by Mr. W. F. Grahame, seconded by Mr. H. J. Leitch.

Rejoined.—A. J. Farquharson, Esq., Tea Planter, Gowhatti.

Contributions.

1. Proceedings of the Boston Society of Natural History, Vol. 19, Parts 3 and 4, and Vol. 20, Part 1, Memoirs of Ditto, Vol. 3, Part 1, Nos. 1 and 2. From the Society.

2. Notes on Tea and Coffee Fertilizer, prepared by David Waldie. From the Author.

3. Memoirs of the Geological Survey of India, Vol. 15, Part 2. Records of Ditto, Vol. 13, Part 2. Memoirs of Ditto, *Palæontologia Indica*, Vol. 1. Part 5. From the Superintendent.

4. Journal of the Asiatic Society of Bengal, Vol. 49, Part 2, No. 1, and Vol. 49, Part 1, No. 1, and extra No. to Part 1 for 1878. From the Society.

5. Plants and seeds from the Nicobars. From E. H. Man, Esq.

6. Seed of the yellow flower variety of the Dhak (*Butea frondosa.*) From J. V. Sturt, Esq., v.p., Municipal Committee of Mau, Ramporo. Mr Sturt remarks that it is a rare variety, and very pretty seen in blossom alongside of the common or scarlet variety.

7. Seed of *Millettia ovalifolia*, from Rangoon. From R. Rowett, Esq. This is a handsome tree and supposed to furnish the "Moulmein Rosewood."

8. Seedlings of *Amherstia nobilis* and plantain shoots from Moulmein. From C. Ady, Esq.

9. A quantity of Mahogany seed. From Dr. G. King.

10. Bulbs of *Eurycles Cunninghamii* and seed of *Acronychia Baueri*. From L. Bernays, Esq., v.p., Acclimatization Society of Queensland.

Report on New Ploughs.

A second report of a Sub-Committee of the Council (Dr. S. Lynch, Mr. W. H. Cogswell, and Baboo P. C. Mittra) in respect to trial of certain ploughs, was read as follows :—

Your Committee presented their preliminary report at the general Meeting in March last on a plough submitted by Mr. Martin of Etawah, when it was resolved that another trial be given to this and any other ploughs submitted for competition, when the rainy season had fairly set in.

Accordingly, on the 23rd June, your Committee met again at the Society's garden, when the following ploughs were arranged for trial :—

1. A combined plough from Mr. Martin, of Etawah, single handle, weighing about 12 seers, selling price, Rs. 8 at Etawah, in Calcutta, Rs. 4.

2. A plough from Mr. Crawley of the Cawnpore Model Farm, made of wrought iron, weighs 14 seers, said by the maker to plough 6 inches without any pressure whatever being used by the ploughman, the cost of making will not exceed Rs. 5, single handle.

3. A plough from the central prison, Benares, double handle, and no beam, cost Rs. 13.

The land on which the trial was made may be termed grass land. It had never before been prepared for any purpose, the grass was in most parts short and close, elsewhere long and jungly. Sufficient rain had fallen to render the ground soft and practicable for ploughing purposes.

The cattle employed were the ordinary village plough bullocks.

With respect to the Benares plough (European in all respects, except in the absence of the beam,) it was found to be beyond the powers of bullocks of the above description owing probably to a defect in the shape, the soil clogged at the shoulder of the mould board, increasing the draught whilst the soil was not turned over; when it was attempted to increase the depth of the furrow, the heel of the plough was lifted off the ground. This is one of the results of the absence of the beam. Another is that the ploughman's command over the plough during heavy work is lost owing to the absence of leverage. The body of the plough is a heavy inert mass in the ploughman's hands. The width of the furrow with this plough is about six inches. The depth could not be fairly stated from the trial.

This plough might go through light soil previously worked without any difficulty.

The Cawnpore plough, in like manner, cutting a furrow of six inches in width by about four inches deep, was heavy in draught, and failed to invert the soil. The mould board was clogged all the time.

The plough from Etawah (Martin's) performed its worked efficiently. It showed a light draught well within the power of the little Bengali bullocks; it turned the slice completely over, making a furrow of a depth of three inches, with a width of 4½ inches. This plough, whilst it resembles most nearly the native type in construction and cost, makes a close approach to the European plough in the mode in which the work is turned out. But there is the radical fault in this and other ploughs with fixed beams, that at the moment when the work is heaviest, the heel of the plough will be drawn up and the point depressed to such an extent as to tax severely the strength of the ploughman.

Resolved that copies of the above report be sent to the parties interested.

Rheea Fibre.

Submitted certain papers on the above forwarded by the Secretary to the Government of Bengal, with a sample of Rheea fibre referred to therein. Mr. Mackenzie adds: "that the Lieutenant-Governor would be glad if he could be favoured with the opinion of the Society as to the commercial value of the fibre and its suitability to the Indian and home markets."

From Messrs. Burrows, Thomson, and Mylne of the Jugdispore Estate, Boheea, dated 8th April 1880.—"In reference to the recent competitive trials at Saharunpore of machinery for extracting the fibre of the Rheea plant, it may be interesting to his Honor, the Lieutenant-Governor, to know that the fibre has been prepared many years ago at Bhagulpore by some families of the Dhanook caste for the silk-weavers there.

We were aware of this, and at the time of the recent competition sent to the President of the Government Committee, sample of Rheea fibre prepared by the Bhagulpore method, with a description of the process.

It was also suggested that this process might be beneficially carried out by the female members of poor Rajpoot and Brahmin families who are not allowed to appear in public or engage in field work. There are great numbers of such families whose women have literally nothing to do.

Clean Rheea fibre brings high prices in Europe and is valuable as compared to its bulk.

The plant is perennial, and the cultivation similar to that of sugarcane without the labor and expense of yearly planting. The roots properly attended to will give three or four cuttings yearly in this part of the country. If left in the open field cattles don't graze it. These are desirable qualities in the estimation of Rajpoot and Brahmin cultivators.

We have procured roots from the Saharunpore and Calcutta Government gardens, with the intention of doing what may be possible, to introduce a valuable industry among the Rajpoot and Brahmin families, resident in the villages of the Jugdispore Estate.

A small sample of Rheea fibre from plant grown here and prepared by the Bhagulpore process, is herewith enclosed for the inspection of his Honor the Lieutenant-Governor."

From the same, dated 19th September 1879, *to the President of the Rheea Committee, Saharunpore.* Rheea Fibre.—The method for obtaining this fibre, practised by certain natives of Bhagulpore of the Dhanook caste some eight or ten years, or still further back, is generally as follows :—

The site of the little factory is chosen, if possible, near a stream of soft water, as the process is one of slow boiling or simmering, and beating in combination with washing.

The factory plant is an earthern or other pan or boiler, and two notched boards, such as *dhobies* use.

The work-people—two men, two women, two boys.

The boiler is charged with water sufficient to cover the shoots proposed to be dealt with, and to it is added about 10 chittacks *sujjee-muttee* for a maund of plant placed in the boiler, the whole is then allowed to simmer or boil slowly for half or two hours.

The shoots are then taken by or handed to the nearest man with a notched board before him (the boards being placed near by or partially in the water *dhobi* fashion) in such portions as can be held firmly between his two hands; he continues to dash it against the board, washing it at the same time, thus clearing each end alternately of the wood and portions of the bark and gum. The handful is then passed on to the second man with a similar board who beats and washes it in the same way to free the filaments still further from gum and bark.

After this it is taken by the boys back to the boiler to be again slowly boiled or simmered for about an hour. It is then again beaten and washed by the two men as before till the gum is removed and the filaments are free.

The two women now take charge of it to be dried, beaten, and drawn or carded till it is in the condition of the accompanying sample, but much whiter.

A maund of shoots per hour can thus be easily worked off, which, its filament is in the plant in the proportion of 2½ per cent., will be one seer

of fibre fit for spinning by the native hand-method or for the carding machinery sent to Europe. If the percentage of filament in the plant is over 2½ per cent., the outturn will be increased in proportion, while no addition is made to the cost.

By adding half the original quantity of *sujjee-muttee* to the water in the boiler, it may be used again, afterwards the water should be changed.

We propose introducing the domestic cultivation of the Rheea plant and preparation of fibre to the people of the villages on the Jugdispore Estate in the hope that it may make a considerable addition to the family earnings especially to high caste families, whose women are, as a rule *purda nashin*, and to whom it seems the preparation of the fibre would be a profitable means of passing time otherwise useless. The plant being perennial and handy, would require little care from the men beyond perhaps loosening the surface and weeding every two months and giving some manure twice yearly.

Should any simple machine be required or found to be beneficial, we have reason to believe that the want will be met by two small rollers on the principle of the native *chirkee* or cotton gin roughed on the surface and working at different degrees of speed ; this has been found to loosen and partially remove the bark, and to some extent freeing the filaments from the gum or gluten by the drawing or triturative motion of the rollers so adjusted to each other.

In addition to our memorandum on Rheea fibre, handed to you yesterday, we will be glad if an opportunity can be given during November and December next of testing on a reasonable large scale the Bhagulpore method of preparing Rheea fibre, at or near the Botanic Gardens, Calcutta, where, we believe, a considerable quantity of Rheea plant is grown.

Report by Mr. W. H. Cogswell.—I consider this sample of Rheea to be one of the best that has been submitted to me for a long time past, as regards its color, cleanliness, and soft silky fibre, and its comparative freedom from gum and mucilaginous matter. The fibre, has not been destroyed by chemicals, as is so frequently the case in many processes, and I think but very little injured or weakened in its strength under the simple method is said to have been adopted in its preparation. It is excessively short, owing, I think, to excessive hackling or combing, and a great waste must have been the consequence. Its value in consequence will be materially lessened. It is, however, admirably adapted for spinning, and I would recommend that in the absence of spinning and weaving steam machinery a sample of cloth be prepared by hand. It is beyond all doubt, of great commercial value in Europe, for blending with silk fabrics, and I advise that a good large sample be sent to England to be properly and carefully valued, which, I think, it is quite impossible to arrive at in this market.

Note by Mr. W. Stalkartt.—I quite agree with all Mr. Cogswell has written above.

Report by Mr. S. H. Robinson.—I agree with Mr. Cogswell's remarks: but before sending the sample to England for valuation in the home market, I think Messrs. Thomson, Burrows, and Mylne might be asked at what rate it is usually sold in the Bhagulpore district, and the rate quoted to the English dealers to whom it is proposed to send the sample.

HINGLI TOBACCO AND ALOE FIBRE.

Submitted certain specimens of the above, obligingly forwarded for the inspection of the Meeting, by Mr. H. H. Locke, Secretary to the Economic Museum, with the following note thereon :—

Here are the samples of—

1. Hingli tobacco.
2 and 3. Aloe fibre, combed and uncombed.
4. And matting made from the Aloe fibre,

which you thought your Society would like to see to-morrow.

I subjoin some short notes about these things :—

The Hingli tobacco was received from the Magistrate of Nuddea. It had been exhibited at the Ranaghat Exhibition in January last, and was sent to us at the end of April. On the 10th May it was thus reported on by a Calcutta expert :—

'A very good sample of Hingli tobacco. Sweet and well cured, comparatively free from stem, worth in Calcutta to-day (10th May) Rs. 9 to Rs. 9-8 per maund, or say Re 1 more than good ordinary Hingli.

'Owing to the weight of stem natural to this quality of tobacco, it is not suited for European markets.'

The Aloe fibre and Matting comes from the Hazareebagh Jail. Dr. Cobb the Superintendent, writes concerning the Matting that

'It is of very superior quality ; is everlasting in wear, and looks well to the last. Is especially suited for passages, or the aisles of churches or public buildings ; ship and steamer saloons, &c.'

Its price is Re. 1-4 a yard. Some excellent samples of lines and twines made from Aloe fibre, were also sent by Mr. Winter,' the Jailor of the Hazareebagh Jail, for transmission to the Melbourne Exhibition. I am sorry I cannot send you samples of these, but the specimens I received were too small to admit of portions being retained for permanent deposit in this Museum, and the original samples have been despatched to Melbourne.

SEED POTATOES FROM MELBOURNE.

The Secretary drew attention to ten cases of seed potatoes just received from Melbourne, through the kind intervention of Messrs. Anderson Wright & Co. These potatoes are in excellent sprouting condition, but having arrived too early in the season for Bengal, it was agreed to distribute them to residents at Darjeeling and other hill stations, and ask them to send down a portion of the produce for trial in the plains in the cold weather.

The best acknowledgments of the Society were tendered to Messrs. Anderson, Wright & Co., for their kind assistance.

PROPOSALS FOR THE DESTRUCTION OF THE TEA BUG AND OTHER INSECT PESTS IN ASSAM AND CACHAR.

The Secretary next read a letter from the Under-Secretary, Government of India, Home, Revenue, and Agriculture Departments, forwarding, as requested, certain papers connected with the above important subjects. The papers consist first of a memorial from certain proprietors and agents of tea properties in Cachar, parts of Assam, and other districts, respecting, the serious extent to which the tea industry in India is being injured by blight, caused by an insect known as the tea bug, and requesting the services of certain Government officers, botanical and entomological, being granted towards an inquiry into the whole subject Then follow—*secondly*, correspondence between the Governments of India and Bengal and the Trustees of the Indian Museum ; and *thirdly*, other communications resulting in the deputation of Mr. Wood-Mason to Assam for the purpose of investigating the injuries caused to tea plants by the tea bug, and the best means of destroying the pest.

In connection with the above, the Secretary drew attention to the great interest the Society had previously taken in the subject. For several years past, it would be in the recollection of most of the Members present, he Society had been receiving communications from the tea districts regarding the great and annually increasing damage caused not only by the tea bug but other insects. In view of these numerous notices, the Council suggested to the Society in 1876 the advisability of taking some steps towards endeavouring to remedy this annually increasing evil. The recommendation, it would be remembered, took the form of endeavouring to engage the services of a practical entomologist to travel over the tea districts of Assam, Cachar, and Darjeeling for two years, to study carefully the character and habit of the various kinds of blight in their several localities, and so be able, probably, to suggest some remedial measures of a practical nature for modifying if not entirely eradicating, their ravages. For this purpose it was estimated that a sum of Rs. 15,000 would suffice, which could be easily raised by agents of various gardens agreeing to subscribe Rs. 10 for every hundred acres under cultivation. The amount to each would thus have been trifling, even if the results were not successful. The Society, moreover, engaged to secure the services of a competent person and to publish, in due course, the result of his inquiries, supplementing it with a *resumé* of the papers already collected and published in their Proceedings and Journal during the past eight years. Notwithstanding the Circulars issued on the subject, combined with personal application, this proposal did not meet with sufficient encouragement to enable the Society to take necessary action. Several agents, largely interested were quite willing to support the scheme, provided all would join. As however, many, though apparently well inclined, would not come to any definite understanding, the Society, as intimated in the last annual report, were reluctantly compelled to abandon the scheme.

The Secretary added that he had afforded all the information in his power, in the early part of the year, to the originators of the above recent memorial to the Government of India.

Letters were also read—

From the Secretary, Royal Horticultural Society of London, returning thanks for donation of seeds.

From the Secretary, Bijnor Agricultural Society, offering the cordial thanks of the Committee "for the valuable support the Council of the Agri-Horticultural Society have given them by consenting to supply this Institute with copies of their publications and seeds of field crops free of cost."

MINERALOGY.

THE Board of Revenue draws the attention of all officers to the following orders regarding the right of Government to mines and minerals, as laid down by the Government of India and Secretary of State :—

Except in permanently settled estates, it is presumed throughout India that, in the absence of any distinct judicial procedure or proof of established usage, the State has a right to minerals. The [illegible] of waste lands (whether or not the grants expressly comprise all products above and below the surface) are, in the absence of provision to the contrary, entitled to mines of gold and silver found thereupon, is limited to grantees of waste land " in fee simple," made in accordance with the rules framed upon the instructions given in Sir Charles Wood's despatch No. 14 of 1862. Grants of waste land in fee simple are, however, no longer made, and all leases of waste lands are now distinctly given subject to reservation of the full right of the State in mines and minerals, and of right of access and other reasonable conveniences for working them on behalf of Government or the assignees of Government.

ONE of the passengers from Bombay by the P. and O. steamer that leaves to-day will be Mr. Brough Smyth, who has been summoned by telegram to London to consult with the Directors of the Gold Mining Company to which Mr. Smyth has been appointed Managing Engineer. We believe that Mr. Brough Smyth's experiments on stone brought from the Comany's land have been highly satisfactory and encouraging to future operations.

IT is stated that a French Indian Gold Mining Company is in course of formation in Paris.

ACCORDING to the *Indian Railway Gazette* an important discovery of coal has been made by Mr. Mitchell, Supervisor of the Candahar State Railway at Sharagh. The coal is said to be in abundance on the hills about the station, and no trouble will be experienced in the getting of it, as it is said to be plentiful near the surface. It is now being used instead of wood in the railway workshops, and is said to contain a great deal of gas and to burn better than any other coal yet produced in India.

IT has been determined to add a series of specimens illustrating the geology and mineralogy of Ceylon to the Ceylon Court at the approaching Melbourne Exhibition. The cost of collection and despatch of the collection has been liberally undertaken by a private gentleman, Mr. A. C. Dixon of the Colombo Academy, who considers that the Australians are likely to take much interest in everything connected with geology.

WE understand that a Mining Company of San Francisco in California intend prospecting for minerals in Travancore and Cochin. They have deputed Mr. W. J. Dermies, who is said to be one who is well qualified for the task, to inspect and report on the geological condition of the two States, and this gentleman is already on his way to Travancore. There has been a general impression that the two States are not without their mineral products; and should the visit of Mr. Dermies prove conclusively that it is so, we expect to see the Company carrying on active operations in Travancore and Cochin before many months are over.

A CORRESPONDENT in Wynaad says:—"Our neighbours in the south-east seem to be in a perfect delirium of triumph over the continually increasing success of their discoveries. Some especially rich reefs have just been hit upon. Everybody is digging holes, and breaking up rocks. Coffee is nowhere, or rather it is anywhere ruthlessly dug up, wherever it in the very least interferes with the one absorbing object; and with the extraordinary finds daily come upon, all reasonable doubt on the subject of the existence of gold, and gold in very considerable quantities in Davala, must, I should imagine, be at an end. A new era in the history of Wynaad is opening to us,—and with such incitement it is not possible or probable that energy will be lacking to carry on the work which contains so much of encouragement in its outset. I hear that the band of Cornish miners who arrived some weeks ago, are working grandly, and up to the present do not seem to have suffered from the proverbially evil climate of Wynaad."

GOLD IN WASH-DIRT.

PRESENT news from Ballarat, received by the Australian mail, is interesting. Early in June a lead of wash-dirt was struck which was named the Hurdsfield, and a number of companies were formed to work various pieces of ground in the neighbourhood, in the hope of finding the run of wash-dirt. Several of these companies have already struck it, and it has proved extremely rich. On the 1st July, the East Hurdsfield Company had 141 oz. of gold for the day's washing up. The Central Hurdsfield Company was said to be washing equally well, and the Hurdsfield Freehold Company had 223oz. from the one machine, and one tubful of dirt. On the next morning the latter company was said to have obtained 130oz. from four candle-boxes of wash-dirt. On the 2nd the Hurdsfield Company reported a yield of 583oz. "What astonishes most people in Ballarat is the extent of this immensely rich field of wash-dirt, for though it cannot be expected to cover any great area, yet no limit has yet been proved; and an impression is beginning to prevail, that the early diggers, who followed the deep beds of the golden gutters only, and who, in those days knew nothing of reef-washes, may have left immensely rich beds of high-lying wash-dirt behind them, and that there is just a chance that a great deal of the area on which the City [illegible] again become the theatre of the wild excitement of a quarter of a century ago. This, of course, is mere conjecture, but it is taking so firm a hold of some people's minds that claims along the course of the Golden-point and Gravel-pits and other old gutters are being taken up right into the centre of the city.

DIAMOND PITS.

THE far-famed Golcondah is no apocryphal place that was visited by Sinbad the Sailor, or Munchausen the Baron; but it is a fortress seven miles to the north-west of Hyderabad, the capital of the Nizam's Dominions. It is proverbially famous for its diamonds, yet it has obtained this fame vicariously, for the diamonds which are cut and polished at Golcondah, are usually brought thither for that purpose from Parteal, close to the southern frontier of the Nizam's Dominions, and about sixteen miles south-west of Ellore in the Ganjam district. But there are six other places in the same locality where diamonds are, or have been found. The names of these places are Mallavelli, Alkur, Parthempadu, Pratalli, Wastapille, and Kodavetti Kall. Eastwick relates that:—

"The hollow flat, where the diamond pits are, is a low, dry, gravelly plain, but which has the appearance of having once been a lake. Through this plain no steam flows, and the pools, in its lower part, dry up in March, when the excavation may be commenced, and not before. The pits are in general excavated at the north end of the bank that surrounds he hollow. The deepest are not more than 12 ft., and whatever the depth, a hard mass of rock is never reached. The strata penetrated are—first, a grey, clayey, vegetable mould, about a foot or two thick; below this an alluvium of the following pebbles, rounded by attrition: sandstone quartz, siliceous iron, hornstone, carbonate of iron, felspar, conglomerate sandstone, and a prodigious quantity of concretionary limestone. The diamond is never found imbedded, or in any way attached to any of the pebbles, but always loosely mixed with the other little stones. The detritus, forming the diamond stratum, must have proceeded from the hills to the North, the only hills, in fact, near the place. They are the continuation of the standstone range, which extends east from Banganapilli, Knodapilli, and Mallavelli, in all of which localities the matrix of the diamond is a conglomerate sandstone."

From this locality, the world has been supplied for centuries with diamonds of the purest water. The diamond which Mr. Pitt, the Governor of Madras (grandfather of the first Earl of Chatham) obtained, and which has been long known as the Pitt diamond, was found in Golcondah. It was taken by the Governor to Europe and sold to the Duke of Orleans for £130,000. It decorated the hilt of Napoleon's sword, was captured by the Prussians at Waterloo, and it now belongs to the King of Prussia. It weighs in its cut state 136½ carats, and is said to be unrivalled in its limpidness, and its form. The Kohinoor, the Mountain of Light, was found—according to Hindu legend—in a Golcondah mine. It originally weighed 900 carats, but has been reduced by cutting to 123 carats, and is now valued at £120,661. It is now the personal property of the Queen. There is fair reason to suppose that the wealth of the Parteal region has not been exhausted, and that the appliances of modern machinery directed by men of science may bring to light gems that have not been discovered by rude native processes of search. A rumour has reached us that a scheme is afloat for developing the diamond resources of the Golcondah locality. That it may be worth while to prospect for diamonds is shown by the remarkable facts that the value of Cape diamonds transmitted through the Post Office in the six years 1873-79 was no less than £16,409,417. Besides these gems a large number went to Europe in the custody of the owners, or as freight, and it is likely enough, making allowance for under-valuation that the total proceeds of the Cape mines approximated closely to twenty millions sterling in the seven years. The best Cape daimond is a slightly yellowish, and certainly, inferior gem to the best Indian diamond; yet so great is the demand for the jewel that the world bought the inferior article to the above extent. This seems to indicate that gems of the first quality are scarce, and that if Golcondah should answer the expectations of some sanguine individuals, a great addition may be made to the exports of the country.—*Madras Mail.*

IRON ORES IN MADRAS.

WE quote the following from that interesting and useful book published by Government, "Standing Information regarding the Administration of the Madras Presidency," it will be seen that there are iron ores there, which only require enterprise to make them of great use to us:—

Some remarkable deposits of magnetic iron ores are found in the Salem district. The ores occur in large beds of from 50 to 100 feet in thickness, and the out-crop may be traced for miles. On one hill, six miles from Salem, there are five bands of magnetic iron from 20 to 50 feet thick. In 1825, Mr. Heath of the Civil Service obtained a Government advance and formed a company to establish iron works at Porto Novo near Cuddalore, at Palampatty near Salem, and at Beypore on the West Coast. At the last place the iron was to be obtained from the laterite. The Porto Novo works were begun in 1833, and those at Beypore some years later. The Government gave their aid, but the experiments failed. The causes assigned were the distance of the works from the source of supply, scarcity of charcoal, and various other practical difficulties. Several companies took up the matter, but with no final success. The information that is available regarding native working in iron will be found under the head of Manufactures. Though not of such extent or thickness, yet still of sufficient importance to be of considerable value in any further opening up of the country by rail or canal, are some great veins of iron-ore in the Kurnool district, which occur in the Gunnygull and other smaller ridges near Ramallakota some 12 miles south of Kurnool. The ore is the grey micaceous or specular iron oxide and is very rich. Old workings on pits are common all over the ranges, showing that much ore has been extraced, but only one or two furnaces appear to be worked now at intervals during the year. The great drawback to the evident richness of this iron field is the scarcity of fuel, which however might be obviated by the conservation of the jungle in the adjacent hill ranges.

We have also lead and copper ores, as will be seen from the following paragraphs which we extract from the same publication :—

Lead ore occurs in the Nullamullay range of the Cuddapah district where it was worked very largely in ancient times ; but although the indications of its extent and richness are fairly good, no continuous or, systematic attempt has been made by Europeans to re-open the mines. Mr. P. W. Wall, the Mineral Viewer to Government in 1858, explored these mines, but did not report very favourably of them, though he seemed to consider the percentage of silver large. The latest assay (1879, by Mr. Mallett of the Geological Survey of India) of a small specimen, gave 78 per cent. of lead, containing silver at the rate of 22oz. 7dwt. to the ton.

Copper ores are met with in the Cuddapah, Kurnool, and Nellore districts in old workings, the best indications being in the latter district, near Gunnipenta, where, some 40 years ago, they were important enough to attract European enterprise, but without any successful result. Within the last year, however, attempts are again being made by a Madras Mining Company, both in this region and in the Cuddapah district, to work these and the lead ores. The Nellore mines are considered by Mr. King, the Deputy Superintendent (for Madras) of the Geological Survey of India, not to have been adequately tried, the traces of ore being frequent and promising, while the old attempts have been carried on by incompetent men met by the usual temptations and insalubrity of the climate.

IRON ORES IN CENTRAL INDIA.

As a means of famine prevention, the devlopment of industrial enterprises is to be ranked with, if it should not take precedence of irrigation works and railways ; and among such enterprises none, perhaps, holds out fairer prospects than that which has contributed so largely to British prosperity—iron manufacture.

Everybody knows that there is iron ore in many parts of India, but it is not generally known that in Central India there are ores of that metal of the best quality.

The Central India iron ores are remarkable at once for their purity and their richness. They are chiefly red iron ores and magnetite, containing sometimes manganese, but there are also brown iron ores and siliceous hematite. As all these ores occur in enormous quantities on the surface of the ground, the erection of costly mining works, which is elsewhere necessary, is here not required. Owing to the difficult treatment required for the magnetites, the native iron-makers prefer the soft red iron-stones of a laminated texture, although the former contain a larger percentage of iron. The brown iron ores and the siliceous hematities are used by them only very exceptionally.

Before showing how the Indian iron ores may be utilised without prejudice to English interests, we will give an analysis of the iron ores of Central India, together with some other details.

The magnetites contain 71 per cent. of metalic iron (or 69 per cent. oxyde, and 29½ per cent. protoxyde of iron), the red iron ore from 65 per cent. to 69 per cent. of iron (or 91 to 98 per cent. of oxyde of iron), the brown iron ore 45 to 55 per cent. and the siliceous hematites 10 to 48 per cent. of metallic iron. The few impurities of these ores are small quantities of quartz, clay, and manganese and exceptionally some lime; of sulphur there are but few traces, of phosphorus none.—at least none have been discovered in the red iron ores and in the magnetites.

So much has the exceptional purity of these ores struck observers that somebody, writing of them in a public paper, some time ago maintained that they were pure iron, which is incorrect ; the richest iron ores can never contain more than 72 per cent. of metallic iron. Iron always occurs in nature combined with oxygen, the lowest degree of oxydation being in magnetite. Pure iron might prehaps be said to occur in meteors, but here also it is combined with nickel from 3 to 8 per cent. We know of no ores in the world which are fully equal to those of Central India in purity, in richness, and quantity over a given area.

In general the European iron ores contain only from 30 to 35 per cent. of metallic iron, therefore half only that contained in the red iron ores and in the magnetites of Central India. How great a value is put on pure and rich ores by iron makers may be learned from the circumstance (which should be made widely known in India) that vast quantities of such ores are yearly imported into England, France, Germany, and Belgium, from the south of Europe and more distant countries.

The iron ores of Central India containing, as was said before, no phosphorus, and little manganese, are suitable for the production not only of bar iron but notably also of steel, and especially of Bessemer cast-steel for rails. It is well known that the amount of phosphorus in the ore determines its fitness for the Bessemer process; and if it exceeds ¾ per cent., the steel cannot be converted into rails, which are now generally made of Bessemer steel. Again, ores containing manganese are known to be especially useful for the production of steel for cutting tools. Equally suitable are the pure red iron ores of Central India, containing manganese, for the production of "Spiegeleisen" (specular cast-iron) a kind of pig iron, which is added to the iron in the Bessemer process, and in cast steel crucibles. Great quantities of this article are exported from Germany and Austria, and the price of it is 60 per cent. higher than that of ordinary pig iron. The same is the case with an article called in the trade *acier sauvage* (wild steel), also a kind of pig iron, containing a very small quantity of carbon. This is exported at high prices, from Styria in Austria to England, France, and Belgium, for the manufacture of ductible iron for wire. Now "Spiegeleisen" and *acier sauvage* can only be obtained from the *purest* iron ores, and of these there are inexhaustible mines in Central India. Here we have then a most valuable raw material for exportation which would not interfere with England's commercial policy as regards India, which has hitherto consisted in the principle of taking India's raw produce and returning it to her in the shape of manufactured goods.

Should the art of iron making in the course of time be so far developed as to furnish us with an economical process of making finished iron or steel direct from the ore, that is to say, without the introduction of the blast furnace and fining process, then pure ores would greatly increase in value and become eventually a most important article of export from India.

The following explanation of the present system of iron making will show the importance of the exertions which are now being made towards the obtaining of iron by a *direct* process.

The object of the blast furnace-process is, first, to free the ore from oxygen, then to induce carbon into the article so obtained, and finally, to melt this compound. The product of the blast furnace is thus iron with a greater or lesser percentage of carbon, called pig iron. The next, namely, the fining process, has for its object, on the contrary, the freeing of pig-iron from carbon or the production of a metal free or nearly free of carbon. To the uninitiated the question will at once present itself why these opposite processes are followed—why the reduced ore, *i.e.*, the ore freed from oxygen, is not melted down direct into iron in the blast furnace instead of first infusing it with carbon, and then freeing it from the same by the expensive puddling or Bessemer process.

The reason is twofold : first, because it is difficult to melt down pure carbonless iron. It would require a very great heat of 1,700° centigrade, whilst pig iron, or iron containing carbon, melts with a heat of from 1,100° to 1,400° centigrade, and it is this excess of from 300 to 500 degrees of heat which is difficult and expensive to attain, both as regards fuel and fire-proof material for the furnaces. The second cause of the roundabout process is the more or less impure state of iron ores, especially in respect of phosphorus and sulphur. Opportunity and time for departure must be given to these impurities, and this is done by the repeated melting and manipulating of the stuff in the so-called fining process.

From this short explanation the reader will easily perceive that, in the case of the magnetite and red iron ores, in which we have to deal with either very small or inappreciable quantities of impurities, the question of producing pure iron or steel by a *direct* process is reduced to one for the science of heat to solve. It is a question, in fact, of producing 1,700° centigrade of heat economically. The solution of this question is approaching. The efforts of Siemens, Dupuis, and others in this direction, if they have not solved this problem, have at least paved the way to its solution. But it may be objected that the best iron ores and the largest quantities of them in Central India are of no avail, as there are no coals there ; the reply to this objection is that there is ample wood available. Again it may be objected as was indeed done a short time ago by a writer in the columns of a daily contemporary, that making iron in India with charcoal has been tried and has failed. It is well known, however, that excellent iron has been made in India, for centuries, with charcoal. Those also who know anything of the iron trade, know that vast quantities of iron are made in Sweden and Styria, both for home consumption and for export with vegetable fuel. It cannot be that the price of charcoal in India is an obstacle since it is about three times as high in Styria, for instance, as in India; neither can the failure have been caused by the experience of charcoal making bad iron, for the reverse is well known to be the case. The true cause is not far to seek; it can have been due to nothing else than to ignorance or bad mechanical arrangements, or bad management, or dishonesty, and very likely to all these combined.

It is on the question of vegetable fuel *versus* mineral coal that the future iron industry of India will depend, and in a future issue we shall probably examine the question in detail.—*Englishman.*

BURMAH GOLD.

Some specimens of gold from the gold washings near Shwegyeen with parcels of the soil or sand from which gold is washed, were forwarded in 1853 for examination to Dr. Oldham, the late Superintendent of the Geological Survey of India. The result of that examination was as follows :—

One parcel, said to be the surface-soil, was found to be a gravelly sand, consisting principally of small grains of quartz, minute flakes of bright-colored mica, generally of a golden tint and of pebbles of various kinds of metamorphic and crystalline rocks. A few small crystalline pieces of topaz occurred in the sand, and one or two minute red garnets were also found. Mixed with this, sand was found in small quantities and in minute grains some magnetic iron sand and a few acicular crystals of schorl. The sand in this parcel did not altogether amount to the fifth part of a cubic foot. By simple washing, it yielded 0·75 of a grain of gold in minute flakes. The residue of the sand was then successfully agitated with mercury in order to obtain by amalgamation any particles of gold which might have been too minute for mechanical separation. By this process 0·20 more of a grain of gold was obtained. Consequently, from less than the fifth part of a cubic foot of soil 0·95 of a grain of gold was extracted.

The second parcel contained a yellowish ferruginous sandy clay, looking as if it were the result of the decomposition of the upper portion of [illegible]. This clay was reduced to a fine state of division and carefully washed—the sandy portion, consisting chiefly of ferruginous quartz grains, being separated. The residue was carefully examined ; but no traces of gold were discovered. The fine, slightly sandy clay, which remained after washing, was considered well suited for the coarser kinds of pottery ; it stood the fire well, and it was sufficiently tenacious to admit of being readily moulded.

The specimens of gold consisted of varieties ranging from dust of the finest kind that could be mechanically separated, to small nuggets. Two specimens described as "purchased at Shwegyeen" very well illustrated the mode of occurrence of the gold in its Native State, imbedded in quartz, while the other specimens showed that the general form in which it is found in these washings is in small rounded flakes or flattened plates of various sizes. This gold was proved to be of considerable purity—yielding on careful analysis 9,200 of gold and 80 of silver in 100 parts.

This result, although tolerably accurate was to be taken only as approximative. It was, however, sufficient to show that the Shwegyeen gold was fully equal in value to the average quality of Australian gold.

The occurrence of gold of fair purity being undoubted, the question remains as to the quality in which it may occur, and the probability of its yielding a fair return. If the specimen of auriferous sand were to be taken as a fair average sample of the kind of soil and of the quantity of gold contained in it, it followed, according to Dr. Oldham, that, as nearly a grain of gold was procured from about the fifth part of a cubic foot of soil, a cubic yard of the same sand should afford about 135 grains of gold, or, if the portion obtained by amalgamation, namely, 0·20 of a grain, be excluded, the yield by washing alone should be 101·25, or say, on an average, 100 grains of gold for each cubic yard of the sand washed. This sand being surface soil, and, therefore, easily accessible without the labor of sinking pit or the cost of keeping such pits open, two men could with great ease raise and wash a cubic yard of soil, daily obtaining for their remuneration, 100 grains of gold between them or 50 grains per man for each day's work. As this gold would be worth £3 British per ounce, each man would realise six shillings and three pence (about Rs. 3-2) per diem—a return, doubtless ample for ordinary workmen, but *utterly insufficient to tempt commercial enterprise and capital*. Dr. Oldham, however, qualified his opinion by adding that the average yield of the auriferous soil would necessarily vary very considerably in character and in richness according to the conditions under which the deposits may have been formed. The geological structure, however, of the greater part of the Malayan Peninsular, extending to Arakan northward, so far as known, indicated the probable existence of auriferous deposits throughout the whole extent, on flanks of the central ranges of high ground. The ascertained existence of gold in more than one locality in Shwegyeen and other parts of the Tenasserim as well as the association in these localities of magnetic iron sand with the gold (a mineral so constant an accompaniment of gold as to have earned among miners the name of the "mother of gold") appeared to Dr. Oldham to confirm this reasoning from analogy. The auriferous deposits he had referred to would, he was convinced, occur at intervals throughout the whole range, and that locality then would prove to be very rich.

Judging from the rude manner in which the gold was washed by the people, Dr. Oldham thought that fully one-half of the entire amount of gold contained in the sand was in all probability irretrievably lost. In his opinion it was extremely desirable that some more efficient, yet simple, apparatus for separating the gold by washing and also for amalgamating it with mercury might be introduced into the district, when the greatly increased quantity of gold which would be obtained by the use of such improved appliances, would quickly lead to their general adoption. The gold washings are, however, still conducted in the same rude manner as before.

We have been induced to reproduce the above, written during a late agitation on the subject as it bears upon what is now being talked of about the gold capabilities of this province, the "Aurea Regio" of Ptolemy, and the *Survarna Bhumi* of old.—*Eurasian* (*Rangoon*).

FORESTRY.

A FOREST Conference was held, on Saturday 31st July, at Poona in the Council Hall. There were present the Governor of Bombay in Council, the Revenue Commissioners, and Mr. A. F. Shuttle-worth, of the Forest Department. No definite policy was decided upon. Sir James Fergusson is said to be well versed in forest matters.

WE learn that the Wynaad Planters' memorial to Government for the construction of a line of Railway from Beypore to Mysore has received the cordial support of Government, as both the Chief Commissioner and the Consulting Engineer for Railways consider the line would yield a fair revenue, and would tap the forest resources of Mysore.

REBOISEMENT.

THE Forest Commissioners of France addressing the Chamber of Peers in 1827, thus expressed themselves :—" The denudation of the hills excites everywhere universal complaints. Their sterility through the carrying away of the vegetable earth which was retained by the trees, the diminution of springs, the augmentation of superficial water, the formation of torrents which overwhelm properties situate below these elevated places, these are the consequences of the wood-cuttings made there, and it will be against these denudations that the administration will arm itself with severity." Accordingly laws were enacted to remedy the danger which had been created by the denudation of mountain ranges, hill, and drainage slopes. And the forest administration have with great success conducted operations more especially under the laws of 20th July 1860, and 8th June 1864, for the reclothing with vegetation of the highlands upon which the great rivers of France—the Loire, the Garonne, and their several important affluents have their sources. Thus under the able and energetic working of a staff of accomplished officers supported by an enlightened Government, the re-afforestation of French Alps, the Pyrenuees, the Cevennes, the mountains of Auvergne, and other water-sheds of the country has become a reality in some cases surpassing all expectation. So successfully indeed, has the reboisement of several of the mountain ranges been accomplished that in the Paris Exhibition of 1878, the Government exhibited models, photographic views, maps, drawings, and plans, illustrating the effects of the forest denudation, the different kinds and classes of works adopted for defence against torrents and for eventual reboisement, and finally the beneficial results of these measures. This collection attracted great notice and created profound interest. One set of photographs illustrate the general aspect of the mountains above what was once, and not so very long ago, one of the most fertile valleys of *la belle* France, and they show how the torrents have scoured and cut up the mountain sides, have deprived them of their protecting vegetation, have swept away the soil, and have carried the soil into the valley to cover fields and smother cultivation, and to fill tanks and reservoirs and wells; how the torrents rush down-ward in uncontrolled fury from the rock exposed slopes to interrupt communication by destroying bridges, roads, railways, &c., thus converting civilization into waste, prosperity into desolation, to endanger life by filling rivers and streams with sudden and fierce floods which sweep away homes tea ds and farms, and even inundate and destroy towns. The map of Embrunais shows the public road covered with blocks of stones brought by the torrent from the overhanging slopes. A second set of maps and designs illustrates the different kinds of defence works adopted to fight against torrents and provide for the introduction of reboisement. These works consist of masonry dams across torrent beds, *barrages* or weirs—*contro-barrages* or buttresses—living weirs of stakes wattled with willow branches, dams of earth, dams of dry stone, and many other similar contrivances designed with great skill and ingenuity. Some of these defence works cost a great deal of money; for instance, in the plan of the torrent of Bourget we see a solid stone wall built with hydraulic current about 101 feet long, 25 feet above the torrent bed, having 15 feet of underground foundation and 8 to 9 feet thick, at a cost of £650. Other sets of views, maps, and sketches show the changes which have followed the establishment of defence works, how vegetation has gradually resumed its place, how torrents have gradually disappeared, and finally, how forests begin to cover the mountain slopes. Views of Jabouret show how in less than thirteen years a perfect revolution has taken place. Formerly there were great slopes of blackish marl always slipping away; now they are all covered with trees and with a dense growth of herbage suitable for fodder. Numerous small ravines, once forming so many channels to swell the floods in the main torrent, are now filled up, and the whole basin of the torrent is completely restocked with trees, and this once renowned torrent is now a permanent and harmless stream. The maps confirm what other evidence has established :—*First*, that forests protect the soil so that torrents cannot form and erode it. *Second*, that the removal of the forest renders the soil subject to torrent action. *Third*, that the destruction of forests has entailed and does entail barrenness and aridity in parts of the country affected, and which were renowned for their fertility. *Fourth*, that along with woods, springs, and rivulets disappear and cease to water the parched land. *Fifth*, that the actual temperature of a country is by the destruction of its forests very sensibly increased. *Sixth*, that the rain gradually washing away the vegetable earth from the sides of denuded hills condemns them to sterility, while these latter, no longer able to retain and regulate the flow of water that falls in their slopes, are scored by deep gullies formed by impetuous torrents, while the beds of rivers are at one time dry, and at another filled by sudden and short lived floods. *Seventh*, that even while torrents are in existence, planting, and restoring vegetations to the slopes moderate, the violent action of the torrent and ultimately extinguish it. *Eighth* that when torrents have been extinguished, the renewed destruction of the forest may re-awaken them into dangerous activity. Thus it will be seen that the importance of placing all the hills, mountains, and drainage slopes of a country under strict forest protection, cannot be exaggerated. Nature clearly intended that her reservoirs for the storage of water for supply to and for the irrigation of the cultivable lands in the valleys and plains should be placed upon the higher levels of the country; and where these natural reservoirs have been thoughtlessly and wantonly destroyed by man, there has Nature always exacted a terrible revenge But forests and trees upon the plains, also, more especially in a tropical climate, exercise equally important influences on the condition of countries, and well may it then be said that not only the prosperity, but the very safety of a country is dependent upon the proper conservation of its forests. So great value and importance does Austria attach to her forests that they are called the sources of the nation's wealth; while in Germany it is the natural belief that as trees are rooted in the soil, so is the welfare of the German people with its roots bound up in a perfect system of forestry.—*Bombay Gazette.*

GARDEN.

LARGE trees, especially tall poplars, placed near a house may serve as very efficient lightning conductors, but always on the indispensable condition that there is no well or running water on the opposite side of the house, for in that case the electric fluid if it struck the tree might pass through the building on its way to the water. In 1864 a house at Lancy, almost in contact with a poplar on one side and a marsh on the other, was set on fire by lightning, and the path of the electric fluid from the point at which it left the tree across the roof of the building to the marsh could be distinctly traced. Hence, in erecting lightning conductors, it is desirable that their lower extremities should terminate in a stream, a well, or a piece of damp ground.

A FERTILIZER FOR STRAWBERRIES.

An experiment made last year by myself may not come amiss at this time with those who grow strawberries. I procured a half hogshead, filled it with rain water, and put into it one-quarter pound ammonia, and one-quarter pound common nitre. When the strawberry plants were blooming out, I gave them a sprinkling of the solution at evening, twice a week, until the fruit was nearly full size. The result was double the amount of fruit on those plants the liquid was applied to, than was obtained from those right alongside where none of the liquid was applied. Let all give it a trial.—*Selected.*

FERNS IN THE NEIGHBOURHOOD OF BOMBAY.

The messman at Khandalla Travellers' Bungalow writes to me, under date of July 19, "that for the last three days there have been very few showers, that the rain when it falls is not heavy, only drizzling. The fog occasionally spreads over the place but does not last each time more than fifteen minutes." He concludes his letter as follows :—"The weather is clear and pleasing for the visitors of Sunday passers." I hope the meaning of this sentence will be clear to your readers : it is rather vague to me. I passed through Lanowlee the other day on my way up the line. I bought a magnificent bunch of growing maiden hair, silver, and hard ferns for four annas. The collectors of these ferns should be encouraged. They have to trudge away to the hills two or three miles off, and take their chance of a stray customer. They sell the ferns with plenty of root, so that they are sure to grow when potted.

Though the Khandalla hills are very prolific of ferns, yet the variety is not so great as at Matheran, where one year I collected more than twenty kinds. The most beautiful and rarest of these is the climbing fern, which can only grow as a creeper up the stalk of a friendly sapling. The leaves of this fern are of a most unusual shape, being very much in appearance and size like the human hand. I have only found it in Elphinstone valley in the thick jungle below Hart Point, and even there it is rare and difficult to find. I am told it has been seen growing on Sion Hill near Bombay, and one year I found it growing in profusion in the Tulsi valley near the new masonry dam. This was during an expedition some day made to the Kennery Caves, which are just below the Tulsi valley. This fern grows only on red soil, and thrives well in Bombay. The pot should be suspended in the verandah or hung under a mango tree ; the fern climbs the strings and hangs over in festoons. A strong plant will climb as high as nine feet, and as the leaves keep green all through the year, it is very pretty. If any of your readers feel inclined to prospect for this fern the monsoon is the time, when a visit to Tulsi and Kennery is most enjoyable. In cloudy weather one keeps cool, and the chance of a smart shower adds zest to the expedition. I have found the fern *above* the masonry dam on the south side, and *below* the dam on the north side. The roots can only be got out with an iron tool.—*Cor., Times of India.*

TEA.

The imports of tea to Great Britain in June and in the first half of this year exceeded those of the same periods of last year by 2,435,636lb., and 16,794,067lb. respectively. The figures were 4,728,237lb. against 2,292,601lb., and 54.424,937lb. against 37,630,870lb. A comparison of the deliveries for home consumption shows an increase of 4,872,736lb. for the month, but a decrease of 8,701 832lb. for the six months. In the former case the quantities were 12,226,451lb. against 7,353,715lb., and in the latter 78,224,094lb. against 86,925,926lb. For the month, the exports show a considerable improvement, and were 4,101,960lb. against 2,421,271lb. For the half-year, they were 17,346,200lb. against 17,862,491lb. The stock in the bonded warehouses was 61,332,811lb. against 49,092,387lb.—a surplus of 12,240,424lb. instead of as was predicted in October last by some of the trade a still larger deficit.

The prospect of war between Russia and China has raised the question how such a war would affect the tea industry in India, if indeed it would affect it at all, and we observe a letter on this subject from the London correspondent of a contemporary whose energies are entirely devoted to tea, in which this question is discussed to the exclusion of every other. The writer is apparently either entirely ignorant of, or has quite forgotten, the existence of certain Treaty ports. He takes for granted that the great European Powers will not be able to prevent Russia from blockading the whole sea coast of China if she can, and that there will thus be a chance for Indian tea. We ourselves think there would be a chance for Indian tea if the war broke out, but for a very different reason. We do not think that Russia would do much in the way of blockading, because she is totally unfit to provide a sufficient number of vessels for such an immense sea-board, and because she has no control over the Treaty ports. Hence her efforts at sea would be devoted towards intercepting the arrival of military stores, and such tea as is made in China would find its way out in the usual manner, but we do not anticipate that so large a quantity would be made. The people's attention would be distracted, and trade relations generally dislocated, and industry never prospers simultaneously with war in any country. The customary advances would not be made by the hongs in the several shipping ports, at least they would not be made so freely, and thus the entire industry would suffer. In this way we fancy the tea industry of India would have a chance, and no doubt the various tea companies would be eager to avail themselves of the opportunity. This we are afraid they would not be able to do, because of the present system of manufacture. Any deficiency that might arise in connection with the China tea crop would consist of the finer qualities. These require considerable trouble and cost in production, and the general disorganisation of the interior would tend to everything being done in a hurried and perfunctory manner. The necessary attention and time would not be bestowed on the manufacture of the finer qualities, which would hence be deficient in quantity, and what is sent forward would not be so good as usual. But what have our tea-makers to offer instead ? Practically nothing that would suit the English palate. The finer qualities of Indian teas are made with a view to mixing with China tea, and are not adapted for being drunk alone. A tea-planter who is in the habit of continually tasting newly made teas at all hours of the day and night, may relish this class of tea, as we know the majority of planters do, but the taste of the general public, not having been thus educated, will not have it. The tea is made with a view to the development of pungency rather than delicacy of flavour, and the ordinary palate prefers the latter.

Why do Darjeeling teas sell so well ? Simply because they are made with a view to their being drunk pure and unmixed.

When an article is produced in greater quantity than the demand warrants, stocks rise and prices fall, and we naturally look to find that particular variety of the article which offers the smallest intrinsic value to the public suffering the most. This is not the case with Indian tea, which is vastly superior to the China article, even after making allowance for the increased price it realizes in open markets, but the artificial way in which the whole business is conducted leads to the abnormal result of the rubbish being sold and the good article lying in stock. This state of affairs will not be put to rights till Indian teas are sold pure and unmixed, at their fair market value of course, and manufactured with that view. Then we may look for a healthy trade, and something like a return of the palmy days of tea in India.

Complaints still continue to be received of the adulteration of China teas. "Highly faced with Prussian blue and turmeric, foreign leaves present, sand; magnetic oxide of iron, clay, withered leaves, faced nutshells, redbole, and sulphate of lime,"—such, according to the *Melbourne Argus*, are a few of the ingredients contained in China importations intended for Australian stomachs. We hope our friends relish the mixture. But it seems that there is a limit to the colonists' power of endurance, and we are told that so far from the Victorians drinking the above mixture themselves, it is re-exported from Victoria to tea-drinkers with "less money or less discrimination." Who the ultimate consumers of this stuff are we should be curious to know. They must have stomachs like ostriches. And yet the *Melbourne Argus* asserts that tea imported from China is on the whole "well worth drinking, and well worth the money." We are afraid our contemporary gets a little confused when writing on the subject of tea. We pointed out the other day, the strange incoherency of some remarks this paper made on the Australian wants as regards tea. "Indian teas" said the *Argus*, "which have hitherto come to Melbourne, have, as a rule, been dearer by 5*d*.or 6*d*. per lb., than the teas ordinarily consumed here ; cheaper kinds than these will of course be sent, for it seems to be now understood, by the persons interested, that *there is no demand for the high priced kinds in Australia.*" A little further on, in the same article, the *Argus* adds :—"*Pekoe Souchongs and Pekoes would be the best varieties to send. The common Souchongs and Congous are too rough to suit the Australian market.*"

Here is another specimen of ignorance taken from the *Daily Bulletin*, a New York commercial organ, from which we should have expected better things. "The Indian teas though lacking the mild flavour of the Chinese plant, have decided merits ; they are one-third stronger, can be sold cheaper, and are unadulterated." Now in the first place we are curious to know what sort of a flavour the *Bulletin* refers to. It must be, we should think, the flavour produced by the Prussian blue, &c., &c., as enumerated above. In the course of the comparison it institutes between the products of the two countries, the *Bulletin* says that Indian tea "*can be sold cheaper.*" If this were so, we should very soon see Indian tea assert its proper place in the markets of the world. But it is not the case, although it is now being sold at prices that are ruinous to the growers. It is generally well-known—indeed it is perhaps the chief obstacle that hinders the largely extended consumption of Indian tea—that we cannot sell as cheaply, quality for quality, as the Chinese can, and principally for the reason that our system of classing is so different. But, for all that, we look hopefully forward to the time when Indian tea will have a fair trial everywhere and be judged on its own merits, which it can very well afford to be. Meanwhile, this very practice of adulteration

of tea in China, will doubtless hasten the time when Indian tea will supplant it. The Heathen Chinee may take the warning, however, which our Government have more than once impressed upon him in connection with this subject. It was not so long ago that 7,000 chests of dust-filings and maloo mixture, miscalled tea, were burnt by order of the English authorities. Such measures as this must, no doubt, have a salutary influence on Chinese tea merchants, and they may, therefore, abandon these malpractices as they see people's eyes opening to their impostures, and the trade in consequence slipping, past them.

It is said that some of the great co-operative stores in London are beginning to practice the sublime mystery of "mixing." A correspondent of a contemporary writes:—"I lately purchased at one of them what pretended to be 'pure Indian tea,' and I am very much out in my reckoning if the stuff was not largely composed of Chinese Congou that had done duty in the pot at least once before. There could not be a *stronger proof* of the estimation in which Indian teas are now held, than the frequent announcements one sees in grocers' windows of real 'Himalayan Souchong' 'genuine Assam Pekoe,' and other similar rarities. Not that these goods are really on hand, but the enterprising traders, quickly recognising the public demand for the Indian herb, endeavour to pass off their celestial atrocities under that name."

We give prominence to the following extract from a report on Indian teas by Messrs. Gow and Wilson, dated London, 3rd August:—

"As there is every prospect of a large increase in the yield of Indian tea, it becomes a matter of serious consideration to all interested that the demand should, in like proportion, increase also. In our opinion there is but one way in which this end is to be obtained, namely, by producing an article which can be consumed pure, and unmixed with its China rival. A gradual but entire change seems to have come over the style of manufacture, of late years, and it is now a difficult matter to find a tea which bears the "Old fashioned Assam Tea" character. The main object appears to be to convert the leaf as quickly as possible into dry tea, without regard to the fact that in the process of manufacture certain chemical changes must be allowed to take place in the leaf, if the bright ruby liquor and a full and good flavor is to be obtained. We know that in some gardens insufficiently withered leaf has been rolled and fired off in a very short space of time, without any regard to what used to be called "coloring" or "fermentation;" it is then as expeditiously sorted, refined, and packed, and the result is that a quantity of the tea that comes to the market, though pungent, is thin and uncured. This we may say is scarcely the description of tea that can be drunk pure and unmixed. We do not advocate the manufacture of teas without pungency, but we must have thicker and richer tea than is now sent. More time and pains ought to be bestowed on manufacture, especially, on the withering and final firing, which latter operation used to take eight or even ten hours, but is now performed in about thirty minutes."

Our American cousins appear to be going ahead in the production of tea. The *Home and Colonial News* tells us that four samples of exceedingly well made teas of American growth have been received in Mincing-lane, for examination and report on behalf of the American Department of Agriculture. The teas were made by Mr. Jackson, formerly of Assam, on his estate in Georgia. The Pekoe and Pekoe Souchong are reported on as being remarkably fine in liquor as well as in leaf, and in a good market would command a long price; while the Souchong and Congu are reported on as being very inferior to the others in liquor, being weak and tasteless. We doubt whether tea manufacture on a large scale could ever pay in America, as labor, in the Southern State especially, is difficult to obtain and very costly.

TEA ADULTERATION.

The Melbourne *Argus* publishes a long article on this subject from which we make the following extract:—

A few weeks ago a discussion was carried on in our columns by means of letters, touching the quality of the tea supplied to Victorian consumers. Letters from correspondents well acquainted with the tea market of the city showed that while there is an extensive manufacture of villainous compounds in China, to be exported as tea, there is at the same time a vast export of really good genuine tea from that country. Also that of the adulterated tea sent out, very little comes here, and when it does come, it does not go into consumption, but is re-exported to countries where the tea drinker has less money or less discrimination. Further, we find that the great bulk of the tea sold here is good, pure, wholesome, and cheap—that if we do not get the best, we get what is good value for the price paid for it, and could only get better by paying a higher price.

As to the comparative merits of Chinese and Indian teas that is not a question easily settled. There are excellent teas produced in both countries, but the Indian teas are dearer, and are new to the palate of English and Australian people, while with good Chinese tea we are well acquainted and have got accustomed to the familiar thing. The pure, strong, pungent; Indian teas appear to be most valuable for mixing with weaker teas so as to enrich and fortify them, and it is most desirable that they should continue to be imported into the colony. But the consumer will not be forced to buy what he does not relish, and of course the importer, the middleman and the grocer, prefer to supply what is in demand instead of exhausting their efforts in a vain attempt to educate the public taste. As a matter of fact, the importation of Indian teas has steadily declined. In 1873-74 it amounted to 77,000 packages, while in 1878-79 it was only 22,000 packages.

In 1877 a series of analyses were conducted in the Technological Museum Laboratory by Mr. J. Cosmo-Newbery, assisted by Mr. Frederic Dunn, to test the quality and genuineness of the tea then sold in Melbourne, and from the recorded results we shall now give a few extracts as a contribution to the tea controversy, premising that the authorities lay it down that:—

"Genuine tea contains between 5 and 7 per cent. of mineral matter, 3 per cent of which consists of soluble salts.

"And that in its ordinary air dried condition pure tea yields an extract equal to 32 per cent., while some choice samples have been found to yield so much as 50 per cent." Accepting this as a standard of quality, we now give a few of the determinations made at the laboratory, beginning with samples of green tea:—

No. 1, classed as "very bad" (2*s.* 6*d.* per lb.), was found to contain, in 100gr., 16·50gr. mineral matter, 28·75gr. extract, 2·00gr. soluble salts, with the following remarks added:—"Highly faced with Prussian blue and turmeric, foreign leaves present; sand, magnetic oxide of iron, clay, withered leaves, faced nutshells, redbo'e, and sulphate of lime were found."

No. 2, classed as "bad," 2*s.* 8*d.* per lb. Mineral matter 12·90gr. extract 26·48gr.; soluble salts 1·86gr. Highly faced with Prussian blue and turmeric, foreign leaves, sand, clay, and magnetic oxide of iron were found."

No. 3, classed as "inferior" 3*s.* per lb. Mineral matter 18·69gr.; extract, 30·95gr.; soluble salts 2·96gr. "Faced with Prussian blue and turmeric; sand, clay, magnetic oxide of iron, and sulphate of lime found."

No. 4, classed as "good," 2*s.* 9*d.* per lb. Mineral matter, [illegible]·89gr.; extract, 31·93gr.; soluble salts, 3·80gr. "Faced with Prussian blue and a large amount of turmeric; genuine leaves, much broken."

No. 5, classed "very good," 2*s.* per lb. Mineral matter, 6·5gr.; extract, 41·28gr.; soluble salts, 3·34gr. "No Prussian blue, nor turmeric detected; leaves genuine."

Now for the black teas.

No. 1, "bad," 2*s.* per lb. Mineral matter, 5·60gr.; extract, 19·57gr. soluble salts, 2·49gr. "Large quantity of stalks and exhausted leaves; small particles of Prussian blue and turmeric."

No. 2, "good," 2*s.* 7*d.* per lb. Mineral matter, 3·70gr.; extract, 30·5gr. soluble salts, 4·90gr. "Leaves genuine and in fair condition."

No. 3, "very good," 3*s.* 6*d*, per lb. Mineral matter 5·12gr.; extract, 45·77gr.; soluble salts, 3·67. "Leaves genuine, no Prussian blue or turmeric."

For comparison with the standard, and with the analysis of Melbourne teas (presumably chiefly Chinese) already given, we add the results of an examination of Indian teas, which has been made by Mr. F. Dunn at the laboratory at our request:—

A—A green tea, about 2*s.* per lb.—Mineral matter. 6·57gr.; extract 41·23 4gr.; soluble salts. 3·31gr. "Very good. Free from adulteration of any kind, and from colouring matter."

B—A green tea, about 1*s.* 9*d.* per lb.—Mineral matter 6·25gr.; extract 41·23gr.; soluble salts. 2·55gr. "Fair quality; soluble salts rather low; leaves genuine, but very large. Free from coloring matter

C—A black tea, about 3*s.* per lb.—Mineral matter 5·86gr.; extract. 32·97gr.; soluble salts, 2·72gr. "Leaves genuine and of good quality."

The practical value of the laboratory tea analysis, of which we have given a few samples, would be greater if we know to what extent the samples examined were representative of the bulk of the tea imported into the colony. In the absence of the information obtained from them is more curious than useful, for while some of the teas found to be of the highest quality may be largely used in the colony, and the worst only to a very inconsiderable extent; still the direct contrary may be the true state of the case. Still the determinations are useful as well as interesting. Of 38 samples of tea examined, 10 were found to yield higher than the standard percentage of extract, *viz.*, 32 per cent, while a few came nearly on to the 50 per cent. only to be found in choice samples. The Indian samples to be seen stand high in this respect, the best containing 41·23 per cent., and the other two respectively 32·16 and 32·97. But several of China teas gave higher percentages, ranging between the standard and 45·7.

It is in their percentage of mineral matters that the Indian teas show best. The standard of genuine tea being between 5 and 7 per cent., the three samples of Indian examined showed respectively 6·57, 6·25 and 5·86 per cent., being as nearly as possible what they should contain to be pure. Some of the Melbourne teas showed very badly in this respect, ranging up to 24 and 27 per cent. of mineral matters. On the other hand some samples had less than 4 and several less than 5 per cent. Where the very large percentage of mineral matters appears, it is due to the presence of sand, clay, magnetic oxide of iron, sulphate of lime, &c. It is to be observed that some of the samples examined at the laboratory in 1877 may have been Indian tea, but there are not likely to have been many of those, seeing how scarce Indian tea was in the Melbourne shops as compared with China tea.

COFFEE.

COFFEE planting in Ceylon is not just now a flourishing industry. The crops of the season 1880-81 will be very short, and a local paper, which has been going into calculations, observes that taking the three main sources of the world's supply together, it looks as though there would be at any rate more coffee in the next twelve months than in the preceding year, and if there be any force left in statistics, we are unwillingly driven to the conclusion that there is but little prospect of better prices being obtained for the bulk of Ceylon coffee in 1881 than in 1880.

THIS year's Java coffee crop the *Straits Times* tells us is estimated at 731,390 piculs. The spread of leaf disease in Java has led the N. I. Agricultural Society to propose to coffee planters there to subscribe to a fund amounting to 250,000 guilders as a reward to whomsoever shall invent a satisfactory remedy for the disease. The managing committee of the Society acknowledges that there is not much hope of finding this remedy which had been unsuccessfully sought for in Ceylon during the last ten years, but holds that some method of extirpating the fungus hitherto not thought of in Ceylon might be discovered in Java. The Merchants' Association at Samarang has taken steps to call a meeting of coffee planters there to discuss the subject and devise measures to check the disease. The Chief Inspector of Government Cultures in an official report on the coffee leaf disease declares that the latter has long been known in Java, its wider prevalence now being due to the long continuance of wet weather. As remedies for the disease he recommends better and deeper cultivation of the soil, especially heavier manuring, to enable the sickly trees to be strong enough to throw off the disease. The Batavia *Handelsblad* calls attention to this plan having been tried and having failed in Ceylon.

LIBERIAN COFFEE.

I.

AS the cultivation of this product nearly resembles that of the coffee of the hills, any remarks as to its culture, &c., may at first strike the reader as superfluous in a country where coffee has been grown so long and so successfully as in Ceylon. But there is as much visionary expectation on the one hand, as there is unreasonable prejudice on the other, for and against it, so that a few remarks, made after a practical study of its cultivation, may be of use in dispelling both. Thanks to Messrs. Oruwell, Agar, and Smyth who ventured on to the unhealthy West Coast, selected and introduced,—in one case at a considerable loss,—Liberian seed in large quantities into Ceylon, there is now no difficulty in procuring seed, each cherry costing not more than one cent., or Rs. 10 per 1,000. There is little to say about the nurseries; provided the seed is fresh, it will germinate readily; be careful to have no drip, plenty of light under the shading, have the beds well dug up, see that the seed is thoroughly soaked, and is sown very shallowly flat side down, and the nursery will be a success. The beds should be kept only damp until the cotelodon is developed; the seedlings should be pricked out into baskets or bamboo pots until they are large enough to plant out, when they should be carefully and cleanly turned out of the basket, or 'split' out of the bamboo, so that the plant with the earth in which it has grown is undisturbed. The holes should be quite twenty inches, and be carefully filled in, ramming down the earth well. As regards the distance which the plants are to be put apart in the field, it will depend partly upon the seed used, and the climate, in our remarks on cacao we said that *with* cacao, Liberian should be planted 15 feet by 15 feet; planted by itself, with the ordinary seed in a non-forcing climate, we think 9 feet by 9 feet the right distance, although with the giant variety, such as *Hooper's crab apple*, we expect 12 feet by 12 feet would not be found too far. Taking 9 feet by 9 feet as the distance apart or 6,000 trees to the acre, the cost of opening one acre will be as under.

Rs. 30	...	...	for Plants
" 8	...	...	" Lining
" 10	...	...	" Holing
" 15	...	...	" Felling
" 8	...	...	" Filling in
" 8	...	...	" Planting
Rs. 74 total			

The plant having once started, the growth of the tree is most encouraging: we know of trees ten feet high in two years; and recently saw a considerable acreage of Liberian, topped at five feet, bearing quite seven cwts. an acre and not more than three years old, the clusters growing where they grew last picking,—a distinct peculiarity of this coffee—and numbering from forty to sixty berries each, one large cluster having as many as 110 berries upon it. The best land for Liberian should be flat, or gently undulating, and well drained, the rainfall should be moderate only, and no shade should be allowed. The seed should be taken from as old a tree as practicable, the bean should be short and round, and the skin comparatively thin. Leaf disease, although shewing itself in the mottled appearance of the smaller branches and some times on the stem, has no appreciable bad effect on the vigour of the tree, or apparently on its bearing, and the crop ripens steadily if slowly.

Regarding the "extreme pungency," of the liquid, so commonly talked about, we maintain it is a mistake, the flavour, though a distinct, is an agreeable one, and, after having become accustomed to it, we can quite conceive people preferring it to the ordinary coffee; the oft repeated assertion that it is not fit to drink, is only one of many prejudices that exist against this product, which will however rise superior to all such attacks; there is no reason why every low country hut should not be shadowed by its beautiful foliage, or why it should not usurp the place of thousands of acres of tangled jungle, affording a sure livelihood to the native, if he has only the common industry to plant it; and to the planter, who is willing to brave the monotony and heat of the plains, it offers, as recent prices will shew, every prospect of fortune.—*Ceylon Times.*

II.

PRACTICAL HINTS ON GROWING IT.

THE greatest care should be used in selecting the seed, which should be taken from old trees, and of long and full-bodied shape, with a thin skin, a fairly sized cherry will not pass through a half inch ring; fresh seed, in a well prepared and carefully tended nursery, will germinate in three to six weeks. The nursery beds should be sown with parchment (the dried cherry will often not allow the germ to appear for a long time and separating the *two* seedlings of the cherry is risky), the small seedlings should be put out into baskets, and when nine inches high, or about twelve months old, may be planted in the clearing. The young plants will require care and shade to enable them to withstand the first shock of open planting; about ten per centum of failures may be expected: supplies will come on readily; the holes need not be more than 18 inches, they must be carefully filled in; planting by turning the plant out of the basket with the earth adhering to the roots may be safely done; in most soils 8 × 8 feet is sufficiently wide apart for the trees, in which case, at two years, 3 cwt. to 4 cwt. per acre may be expected. The crop will not all ripen, the larger clusters will necessarily diminish as the fruit increases in size by being 'pushed out,' and in dry weather many of the cherries will get dried up and light; about 44,000 beans parchment go to a bushel, and say, fifteen bushels of cherry to 1 cwt. coffee. The fruit takes quite one year to fully ripen. Leaf-disease will invariably attack the nursery, but will gradually lose its ill-effects as the tree grows older; when it also will much better resist the effects of drought; well grown trees should be fully six feet high a two years old.

We imagine the most suitable climate for Liberian coffee is that with a mean temperature of 78° to 80°, and a rainfall of 80 to 100 inches in the year; it adapts itself to almost any soil, but on account of its long tap root, prefers a deep black one; in damp soil, it sometimes suffers from bug. It is one of the most beautiful of trees, and yields both crop and blossom on its generous branches at the same time.—*Ceylon Times.*

COFFEE CULTURE IN JAMAICA.

THE following is an extract from an interesting letter of Mr. D. Morris, late of Peradeniya, to the *Ceylon Observer.*

I have been trying to find out why the Blue Mountain coffee of Jamaica is always so good, and how it is that it obtains such high prices as compared with the fine and highly cultivated coffee of Ceylon. Is the coffee grown here a peculiar variety of *C. arabica*? or is there something in the soil and climate, which promotes the larger formation of the essential oils and secretions in the fragrant bean? Whatever it is, it cannot be in the superior cultivation, the more rational treatment of the crop, or the greater care in the curing. The only cultivation which the estates here receive consists in a rough "hoe-weeding," once or twice a year, with no pruning, except what the hoe does, no system of drainage, no terracing, and, as I mentioned before, no manuring! It is true that on one or two estates, such as Radnor, a higher style of cultivation is being inaugurated, but, as a rule, coffee cultivation in Jamaica cannot compare, at all, with what is being done in Ceylon. I say this without the slightest disparagment to the planters of Jamaica; they have had to pass through so many crisis, and to fight against so many adverse circumstances, that, at last, they have been obliged to submit to the inevitable and especially as regards labour, and manage as best they may. It may seem strange to a Ceylon planter, but all the work of pulping, curing, and preparing the coffee, is done here on the estates by the superintendent or overseer, and when the coffee is sent down to Kingston, it is ready for shipment and immediately put in barrels. The system and the absence of large coffee curing establishments must necessarily increase the cost of curing, &c., but it appears to have been pursued here from time immemorial, and planters appear to like it.

Owing to the large areas nominally included under one estate, the different "coffee fields" are sometimes two or three miles away from the works, lying in "bosoms" of the hills, [illegible] for the occasional "hoeing" and picking of crop. Out of a nominal acreage of 1,000 acres, often there are only 160 to 200 acres, and sometimes only about 60 or 80 acres under cultivation. The other parts are in "reccinate" (jungle) or so steep that owing to "breakaways" and rocks it is impossible to cultivate them. This gives a Jamaica coffee estate a very patchy appearance, and as cinchona has not yet been taken up generally by planters, the uncultivated areas greatly exceed those cultivated. Much more might be done with the suitable coffee lands, if a regular system of nurseries was established, and plants put out with greater care. At present new lands are planted up with "suckers" (or rather seedlings) found under the trees. These are pulled up with little or no care, even when they have 6 or 8 primaries, and after being carried in bundles on heads exposed to the full rays of the sun, are put in holes, and allowed to take their chance without shade or shelter. It is strange to hear such plants called "suckers" but that

is the orthodox term for them here, and it is on such plants that Jamaica planters entirely depend for their supplies and for planting up. I was much puzzled the other day with a remark made me by a planter respecting these said "suckers." I asked why these self-sown plants were called "suckers," when evidently they were nothing of the kind. I suggested "seedlings" as an appropriate term, I was told, "No, no, they are not seedlings: a sucker does not become a seedling till it is crowned." This was still worse, and I had to give it up.

With regard to the absence of nurseries and the planting up of land by weekly sown "seedlings," it seems a pity that so much valuable land and so much time should be lost, when the remedy is so simple. The plants thus put in are often 2 feet high, and with several primaries (*i. e.*, crowned, as I found afterwards). Their rootlets are torn and lacerated, and the check they thus receive in transplanting, and in being suddenly taken out from shade and exposed to the fierce rays of a tropical sun, results either in a large percentage being killed or in the plants being two or three years before they produce a maiden crop.

But still, as the planters say, many of the plants do grow, and when, they do, they produce some of the best coffee in the world.

In colour, the best Jamaica coffee is darker and bluer than Ceylon coffee and the beans smaller. Whether the colour shows a larger proportion of oil I know not, but the sample appears to be greatly judged and valued according to colour. The sample sent reminds one, in the size of the beans, of Mocha coffee, only the beans of the latter are generally of a dark yellow colour. Nearly all West Indian and Brazilian coffees are bluish or greenish grey.

The colour of the bean must depend in some measure on the manner of pulping and drying, but so far as I have noticed, the processes in Jamaica are much the same as in Ceylon, except that possibly, here the cherry is allowed to stand longer before it is pulped.

But to return to the question of high prices—Why does Jamaica coffee command such high prices? This subject, and especially in connection with Mocha coffee, must have occupied the attention of coffee planters, ever since coffee planting began, but so far, it appears not to have received a satisfactory solution. Is it temperature, atmospheric pressure, natural fertility, humidity of soil or air, amount of sunlight and excessive stimulation which produces the perfect elaboration of those subtle principles upon which the aroma and active qualities of coffee depend?

With regard to Mocha and Jamaica coffee, there must evidently be a combination of very favourable conditions for the production of beans possessing such salutary and agreeable qualities; but from the subtlety and delicacy of the law of vegetable assimilation, I fear it is almost impossible so to analyse and trace these conditions as to produce their parallel in other coffee-producing countries.

For Ceylon planters there is, however, one lesson which Jamaica coffee may fitly yield. It is a subject of frequent remark in Ceylon, that there was no leaf disease before artificial manures were used, and many good planters believe that if the use of artificial manures had not actually introduced the destructive fungus, it had at least prepared the plant for its attacks, so that it became an easy prey.

I know that the fact that the disease first appeared in a comparatively new district where artificial manures had not been used, considerably weakens this theory, but there can be no doubt that by forcing a plant artificially you introduce new conditions of life which may ultimately prove disastrous. The soil of Jamaica is naturally much richer and stonger than that of Ceylon, and the underlying rocks, composed as they are, of loose and easily disintegrated materials, replace soil lost by waste, with great rapidity; but if the system of *tillage* now pursued in Ceylon had been in existence there generally, fifty years ago, and the rich surface soil had been preserved by drains and terracing, it is quite certain leaf disease would never have been so fatal to the old estates, and with a careful husbanding and manipulation of the natural soil manuring would have been unnecessary, and the coffee trees would have been more hardy—and less prolific possibly—but better able to fight against the attacks of fungoid and other diseases. As far as I have noticed, there is little disease on any of the cultivated plants of Jamaica. With the exception of the *Cemiostoma coffeellum*, a little leaf miner similar to the *Gracilaria coffeefoliella* (NIETNER) of Ceylon, which cause the silvery tortuous markings and blotches on coffee leaves, Jamaica coffee appears to be very free from disease. Our old friend the black bug is here, but it does not give annoyance except, sometimes, to badly cultivated and young coff e.

The "Bourbon" sugarcane, which cannot be cultivated in Mauritius, on account of its liability to disease [illegible] productive cane, and similarly with oranges, limes, ginger, and pimento. Jamaica cannot be accused of having forced any of her products by manures, artificial or otherwise, and it may be —but I would not like to commit myself to the conclusion—owing to this, that the plants here are so free from the common maladies of cultivated plants.

Now that the immigration scheme is working so satisfactorily, Jamaica's great want, an adequate labour supply, is becoming less felt. At the Government cinchona plantations creole labour is both abundant and good. By entering into an agreement and paying regular *weekly* wages, we are able to secure a certain number of regular hands: others are taken on only when they are wanted. There are several thousand acres of valuable land on the Blue Mountains admirably adapted for coffee or cinchona, and they only require men of energy and capital to ensure their successful cultivation. I do not desire to appear as an advocate for general emigration to Jamaica, but for young men with some capital and determination, I believe the splendid climate and cheap lands of Jamaica require only to be known to attract numbers who now go farther and fare worse.

In connection with the high prices obtained by Blue Mountain coffee, it would under present circumstances be very interesting to test its value under cultivation in Ceylon. As far as I am able to judge, the trees themselves do not differ much in habit, size, character of foliage, or in floral organs, from those cultivated in Ceylon, but the plants here, in consequence of good soil and no disease, are undoubtedly hardier, and must possess a stronger constitution than trees which have been subject for many years to the enfeebling effects of leaf disease. I believe the experiment worthy of serious trial on a large scale, and it would give me great pleasure to assist any of your enterprising proprietors, who may be anxious to procure a supply of seed from Jamaica, and plant up some 50 or 100 acres in Ceylon for this purpose. The seed has the merit certainly of being thoroughly sound and good, and if in addition it will keep its superior qualities in Ceylon, it would prove a most valuable acquisition. I know that the small lots of Mocha and Java coffee that have been already tried in Ceylon have been severely attacked by leaf disease, but I have not heard whether the produce has ever been tested, or whether Mocha coffee grown in Ceylon is in any way superior to the plantation coffee. To test the matter thoroughly, it would be necessary to plant up a large area with nothing but the imported coffee, so as to be able to ship an appreciable amount at one time. Plants of Mocha coffee being naturally very delicate, they would consequently be very easily affected by the *Hemileia*: but if, as I believe, the Jamaica Blue Mountain coffee is hardier even than your plantation coffee, while at the same time its produce obtains a much higher price, it seems to me to possess special advantages at this juncture. I offer the suggestion as a contribution to the present discussion on coffee cultivation in Ceylon, and in the hope that by the introduction of "new blood" the *Hemileia* may receive a material check in the higher and more recently opened estates.

The experience gained in the case of the vine disease goes to prove that new and hardier varieties of plants have been able to hold their own, and to thrive in spite of the prevalency of such diseases as the ubiquitous *Oidium*, and it is to this that we owe the revival of grape cultivation in Madeira and other places, where after the dreadful attacks of 1848-52, viticulture had been almost exterminated.

CINCHONA.

MR. MURRAY, the publisher, will shortly issue a book by Mr. Clements Markham on a subject he has made peculiarly his own; "A Popular Account of the Introduction of Peruvian Bark into British India and Ceylon," and he will give particulars of the progress and extent of its cultivation.

A HOME paper states that cinchona red bark, grown in Jamaica, realised encouraging prices, being, in some cases, double those fetched by Indian *C. Succirubra*. Ten thousand pounds of dry, bark were obtained from 2,490 trees, being at the rate of four pounds per tree. A single harvest realised 17*s*. per tree—a result highly satisfactory.

IT appears that the question of a supply of quinine for India, will not be entirely confined to the alkaloid derived from *Cinchona Calysaya* as we have on our table a very fine sample of sulphate of quinine manufactured at Rungbee by Mr. Gammie, from *Cinchona Succirubra*, which is quite as pure as any we have seen of Howard's. We do not think we are over-sanguine when (judging from present results) we predict that the time is by no means far off when India will be able to produce all the quinine required for the public service of the country, and will thus be quite independent of England.

Now that cinchona cultivation is becoming very general and sites for plantations are being eagerly sought after, it is interesting to note every anomaly connected with the growth of this tree. Mr. Hughes, speaking of Ceylon, lays it down, as a general rule, that stiff and tenacious soils should be avoided for cinchona, which flourishes in the island only in rich, friable, or gravelly soils. Elevation also is reckoned important, both there and on the Nilgiris. Elsewhere, however, cinchona appears to thrive under exactly opposite conditions of soil and altitude. In Jamaica, for instance, where the soil is clayey and stiff, *C. succirubra* has been most successfully cultivated, and the recent exportations of bark have obtained high prices. The elevation of plantations there is 2,000 feet above sea-level, an altitude at which our planters would believe it folly to risk the plant. The prejudicial effects of the stiff and impervious soil of Jamaica are supposed to be counterbalanced by the peculiar geological formation of the subsoil, which consists of a porous lime-stone, full of sink—holes, which convey the surface moisture to subterrean rivers. Thus no hard and fast rule can be followed, and the rejection of a site for some accepted disqualification, either on the score of soil or climate may prove a mistake.

We are not aware that the present condition of the Dodabetta Cinchona Plantation has attracted the attention of Government; if it has not yet done so, it ought to do so at a very early date. To a private proprietor the state of affairs would be a source of anxiety, if not of alarm. The whole plantation is overrun with that stringy moss which augurs decay, every bough and twig is covered with it, and the lower ones already form dead wood. The upper boughs have a mere tuft of green leaves, towards which decay is fast travelling. The whole estate is thus overrun. Whether the moss has its origin in unsuitability of soil or in exposure, or whether it has been propagated by the remnants of the old forest left, here and there, scattered over the plantation, it is not easy to tell. The condition of the plantation has attracted attention, and those who have invested their capital in cinchona, would wish to be informed whether such a state of things can be disregarded, or whether it means ruin and loss, sooner or later. The absence of information from Government, scientific or practical, on cinchona culture has been very marked of late. State property of this sort has proved remunerative we know, but beyond this, the public has gathered nothing from official papers worth knowing, and Government has even shown itself not posted in, some of the processes which private owners have learnt and practised.

Cinchona cultivation is now the great rage in Ceylon. The coffee planters, what with leaf disease and other drawbacks, were well nigh driven to despair, when cinchona came as a redeeming angel. But there seems some danger of the new horse being ridden to death. The following extracts from a letter, written by a Ceylon planter to a friend in England, contain some interesting information regarding this cultivation :—"I suppose no cultivation has been so widely taken up and rapidly developed as that of cinchona in Ceylon. It is certainly a most bountiful tree, and has changed the aspect of many declining coffee estates to increasingly valuable properties, and in some cases, notably two, where it has attained too, *regular* growth has brought great wealth to the owners. One local newspaper has given itself almost entirely up to its cultivation, and you commonly hear statistics given, and instances quoted, showing how a hundred acres of four-year old cinchona must be worth £40,000. In fact, the fever is now at its hottest stage. The small leafed variety *Officinalis* I have planted 4,840 to the acre. Say 1,613 trees mature, which at 6 oz. to a tree is equal to about lb. 600 bark, which should be worth say Rs. 900, in four years' time, which means, at an expenditure of Rs. 600, an annual profit of 12 per cent. This is my own estimate. Of course if you are fortunate enough to get fine land with a gravelly subsoil and good natural drainage at an elevation of say 4,000 to 5,000 ft., I know no reason why those enormous profits that have certainly fallen to some, should not also be yours, but it is a venture and in most instances, a terribly disappointing one. To sum up what I have endeavoured to say, I would not advise you with no knowledge of the subject to go into cinchona, but should recommend you to stick to coffee, which to my mind is much safer and generally more remunerative than cinchona, and provided you got into a good district, will give you nearer 20 per cent. than 12 per cent. At the same time I must tell you that the land in which my cinchona is growing is poor, high and exposed, in fact, will grow nothing else, and yet I expect 12 per cent. on the outlay."

A correspondent writes :—"I find no mention made any where of an interesting experiment that has for some time been carried out on Mr. Money's Deva Shola Estate. The bark on a portion of the estate was scraped off the entire stem. Although the dry weather succeeded, the trees thus treated showed no symptoms of injury. The entire removal of the bark from the stem is viewed ordinarily, as an operation so opposed to the accepted theory of vegetable life, that the survival of a tree after it is somewhat of a phenomenon, but in the case under notice, thousands of trees have been so treated without any apparent injury as yet. The foliage of the head is green and fresh, and the bark has renewed with wonderful rapidity. Mr. Barlow, the late Commissioner, spent some time on the estate to ascertain the conditions under which the experiment was being carried out, and the mode of operation. These were duly reported, I believe, to Government, but nothing has yet been made public. Surely there is no more important subject to the cinchona planter than the method of harvesting the bark. Government is apparently unconcerned, but Mr. Money, I should think, might oblige by telling us all about the matter."

THE CINCHONA FORESTS OF SOUTH AMERICA.

At the last meeting of the American Pharmaceutical Association, Mr. Henry S. Wellcome gave a long account of his recent visit to the cinchona regions of the South. Mr. Wellcome expresses much sympathy for the Indian collectors of the bark, describing the climate as deadly, the land as dangerously precipitous and treacherous, and the pay miserably small ; he concludes his remarks by saying that continual wars and revolutions render all investments hazardous, and stagnate all enterprise ; even, when the bark is collected ready for shipment, the roads and ports are often blockaded for months, entailing heavy losses upon the dealers. From his rather copious notes we have extracted the following, he says :—"I shall speak more particularly of the cinchona forests of Ecuador, once the only source of bark, and still yielding large quantities. The bark territory, is divided into the districts known as Bosque de (forest of) Guaranda and Bosque de Loja.

The Bosque de Guaranda is a vast forest, extending from about 1° N. to 2° S., and covers the western slopes of Chimborazo and the outlying range of the Cordilleras to more than 10,000 feet above the sealevel. The district is the source of most of the barks exported from Guayaquil, and has never yet been fully explored. Guayaquil, the main shipping port of Ecuador, is a city of 30,000 inhabitants, situated on the Guayaquil River, 60 miles from its mouth. The river is navigable to this point by large ocean steamers.

The elder cinchona district, Bosque de Loja, was the source of the first barks taken to Europe. It extends from 2° S. to 5° S., the boundary line of Peru, and covers the western slope of the Cordilleras. The district has been worked constantly for over 200 years, and the quantity of bark it furnishes to the Guayaquil market has fallen off during the past few years. Before reaching the highlands, scattered trees of cinchona magnifolia, a valueless species, are met with. Next day our cascarillero soon descried some cinchonas in the distance by the glistening leaves which reflected brightly the vertical rays of the sun.

This characteristic reflex of the foliage, with the bright roseate flower, affords the best means of discovering the cinchonas among the mass of forest giants. The glossy leaf of the India-rubber tree is easily mistaken for the cinchona by a novice, but skilled cascarilleros are usually able to distinguish, at a great distance, varieties, by the colour of the flowers and general appearance of the tree.

At the bottom of the ravine we followed a small stream, till suddenly our guide shouted "cascarilla," and we were gladdened by the sight of several fair-sized trees of cinchona succirubra.

The cinchonas seek the most secluded and inaccessible depth of the forest. They are distributed through in more or less irregular scattered patches, sometimes singly. The older trees are really very grand and handsome, 40 to 80 feet height, trunk straight, branches regular, leaves evergreen, 6 to 10 inches long, of a dark green colour, sometimes tinged with crimson, the upper surface of an almost waxy lustre, flowers in terminal panicles of bright rose tint, and diffusing a pleasing fragrance. The bark of the large trees is usually completely covered with mosses of the most delicate lace-like texture, interspersed with the lustrous variegated lichens and diminutive training ferns. Vegetable growths develop with wonderful luxuriance beneath the interlacing branches, which permit but the faintest rays of sunlight to filter through them. Everything is saturated and dripping with moisture ; the very air we breathed seemed a clammy vapour. The atmospheric changes are continuous and very abrupt, drifting banks of gloomy clouds are followed by glaring sunshine, and then tempestuous showers, all in rapid succession. The temperature is more even, averaging about 65° F., seldom exceeding 80 F., falling below 45° F. ; altitude about 6,000 feet.

The season for bark gathering begins about August 1 (in some forests as early as June), and lasts till October or November ; during these months the bark cleaves most readily, and on account of the smaller rainfall, the forest is more accessible. It is almost impossible to enter it during the wet season. The trees are first decorticated from the ground up as far as can be reached and then, after felling and removing the clinging vines and mosses, the rough outer bark is beaten off with a club or mallet. The bark is then cut round the trunk in sections of 2 feet to 3 feet, and longitudinally in strips of 6 inches to 8 inches in width, then removed with the blade of a machete. The root-bark is obtained by digging away the earth and cleaving with a machete—a large heavy knife.

When first taken from the tree the inner surface of cinchona bark shows a handsome cream tint (with juice of the same colour), but on exposure to the atmosphere rapidly darkens to a dirty red. The barks are usually taken to the main camp for drying and storage. The thick bark of the trunk requires great care in drying because of the excessive dampness of the atmosphere which sometimes necessitates the use of artificial heat to prevent moulding ; it is piled up in tiers with sticks between the layers to allow free circulation of air, and weights are placed on top to flatten it. The thin bark from the young trees and small limbs dries more readily and rolls itself up into quills.

One of the greatest difficulties connected with the gathering of cinchona bark is that of transporting it to the coast at the end of the season. It is roughly sorted, according to the part of the tree from which it is obtained, and packed in bales of about 160 lbs. each ; the Indians carry these bales on their backs a distance of sometimes several hundred miles to a transfer warehouse, from whence it can be transported by mules to the nearest seaport.*

The final sorting and classifying of barks is done at the main storehouses at the coast,† ... packed in ceroons of cow-hide‡, or bales of heavy sacking ; there it is that most of the adulteration and sophistication is done. The admixture of inferior barks with higher grades is not so much the result of ignorance, as has been supposed by many, for the bark dealers are very expert in determining the different varieties and

* The worn appearance of most cinchona barks seen in the market, is produced by the rough handling it gets during transportation to the coast.

† In Bolivia the sorting and packing is usually done before transporting to the coast.

‡ The ceroon consists of a closely-packed bale sewed up in cow-hide (hair side out). The hide having first been rendered soft and elastic by soaking in water, on drying it shrinks and forms a very strong and firm package.

estimating the values of barks; but, strange to say, very few bark merchants ever become wealthy.

All barks enter the market bearing certain brands, such as "J. P." or "T. B." These brands gain a reputation according to the quality of bark they represent, but it is sometimes the case that, as soon as a brand has established a good name, the dealor sophisticates with the inferior grades§. No large buyers of Europe or America purchase cinchona barks without first making careful essays; but, even with this precaution, they are sometimes deceived, on account of the adroit manner in which the barks are mixed.

As regards the prospect for future supplies of cinchona barks from the native forests of South America, the outlook is not encouraging, the greatly increased use of cinchona alkaloids during the past few years, with the consequent demand for a larger supply of bark, has caused a very thorough working of the old forests, and a search after new ones. The discoveries of paying forests are becoming more and more rare every year, and the new forests are found at greater distances from the shipping ports, and are more difficult of access.

The tract of country yielding the cinchona is not so unlimited as some writers would lead us to believe, nor is the supply inexhaustible; it is a fact recognised by natives and dealers who are well informed about the extent and resources of the cinchona bearing district that if the present ruinous system of destroying the trees is continued and no effort made to propagate new growths, they will, before many years, be practically exterminated from their native soil.

With the abundance of seeds yielded by the cinchonas, one would naturally expect young plants to spring up in great numbers, but such is not the case, the light-winged seeds mostly fall upon and adhere to the over-moist foliage, where they quickly germinate and decay, or if, perchance, they fall to the earth, it is almost impossible to gain a rooting, as the soil is covered to the depth of 10 to 20 inches with loose decaying leaves. Beyond all doubt the cinchonas might be successfully cultivated in their native country especially in the localities of the exhausted forests but the natives show no enterprise, and foreigners receive no encouragement from the Government to attempt it. Two Germans have made a venture at cultivating cinchonas near the city of La Paz, Bolivia, but as yet the plants are not sufficiently developed to determine the results.

§ I was told of one merchant who, thinking his brand sufficiently well-established, made a very large shipment of high-grade bark, with which he mixed about one-third of inferior quality; but the trick was detected in the foreign market, and his entire lot could only be sold as inferior grade, causing a heavy loss and serving him a very just punishment.

SERICULTURE.

THE new silk crop in China promises favourable results, and according to the newspapers received from Japan, the crop there also holds out good prospects. The production is expected to be large and of good quality. These facts, coupled with the prospect of a good crop in Europe, tend to show that prices will rule low during the present season.

SILKWORM rearing, to which so much attention and encouragement are now being giving in the Punjab and North-West Provinces, is precisely the sort of industry suited to the Indian ryot. No capital is necessary beyond that needed to purchase eggs, &c.; the methods of rearing are simple and easily understood; the food for the caterpillars is never difficult to obtain in this country; there is, and always will be, a demand for the silk, and a fair, if not high, profit may be reasonably expected. The rearing of silkworm may be undertaken by any one without its interfering with his regular occupation. His wife or children can do all that is necessary.

TOBACCO.

EFFORTS have been made, but not with very great success, to cultivate tobacco of superior quality in parts of Arracan in British Burmah. The soil there is said to be as good as the soil in the Phillipine islands, but the Burmese are too conservative to adopt any new-fangled schemes. It is said that if the Government would take the entire scheme in hand, tobacco cultivation might be successfully carried on, and a decided improvement would be apparent in the quality of the leaf.

THE cultivation of tobacco is being vigourously pushed on in parts of Ceylon, and especially in Jaffna where the crop this year has turned out well, and the Colombo market has received large supplies of the leaf. The quantity in store is very large, and we read of shipments being sent to India. The cultivation of tobacco, it has often been pointed out, is one of the most important industries that can be undertaken. In the southern districts of this presidency, particularly in Madura and Trichinopoly, tobacco is extensively grown, and of late years increased attention is given to its cultivation. The cigar manufacturing trade is assuming some proportions, and shipments of cigars are now made steadily to Burmah, the Straits Settlements, and Australia. In connection with the cultivation of tobacco, Dr. Bidie states in the catalogue which he recently published of the specimens sent to the Melbourne Exhibition, that vigorous efforts have been made to effect improvements in the native methods of culture, curing of the leaf, and manufacture of cigars. The Trichinopoly and Dindigul tobaccos are much alike in appearance and quality, but the Lunkah tobacco, grown in the delta of the Godavery, differs materially from both these varieties. As a rule, the Trichinopoly and Dindigul cigars have a stronger taste and flavour than the Lunkah, but the latter although tasting milder, has a more marked effect on the nervous system, and probably contains more nicotine. The exports of tobacco from the Madras Presidency have increased; in 1878-79 the exports were 5,223,829lb., valued at about eleven lakhs of rupees. European firms have started cigar manufactories, and have produced very good cigars which are used extensively in the presidency, and efforts have been made to send supplies to foreign countries.

TOBACCO.

BE[illegible] that many of those who have applied for land in the [illegible], especially in the Eastern Province, may purpose planting tobacco and also that the industry will become an important and remunerative one in Ceylon, as it has already become in India, we have prepared the following remarks on this subject, bearing on its cultivation here. From the data in the Madras Government papers on the subject, it appears that the three best varieties to be planted are *N. Macrophylia* [illegible] heart-shaped Maryland tobacco, which produces a very fine leaf the [illegible] Turkish leaves being probably the produce of it. N. [illegible] stalkless Virginian tobacco, leaves fiddle-shaped, three times as long as broad this furnishes good leaves for smoking, produces heavily, and is much grown in Germany, *N. Rustica ovata* small-leaved, Hungarian tobacco, leaves small, egg-shaped, and smooth, his variety furnishes fine aromatic leaves for smoking, but the yield is low, and *Nicotiana crispa*, furnishing the leaves of the celebrated cigars of the Levant, stem very much branched and covered with white hairs, leaves small, stalkless and clasping the stem, flowers red; this species is much cultivated in Central Asia, and we should suspect is a variety that should be introduced in Ceylon.

The tobacco plant has so many species and sub-species, some being valueless, that we recommend all care to be used in procuring seed. In 1875 the Northern Province alone exported over 55,514 cwts. (returns of which were made) which at Rs. 25 per cent. represent a value of Rs. 1,387,850, the value of the tobacco grown in the Northern Province is not more than [illegible] cents. per lb. while in India where the cultivation has been well studied it is worth 11 cents., being just double. The higher class of tobacco (as *N. crispa*) is worth as much more again, however, some Sumatra tobacco having lately sold for the equivalent of 90 cents. a lb. This great difference in price will suffice to shew how much will depend upon the seed procured.

We should imagine that the climate of the Eastern Provinces is most suitable for tobacco damp weather even during the harvesting is fatal to the leaf though it is necessary that a certain amount of rain should fall on the plant after being first put out. It is also necessary that the soil be a very light and friable one A sandy soil containing an average amount of organic matter well-drained, is the *beau-ideal* of a tobacco soil Of course the richer a soil is, the thicker and heavier the leaf and the greater the outturn, but this is by no means the object to be attained. The more clay a soil contains, the less will be the aroma, and the coarser the leaf; still even in a clay soil, by proper tillage and digging a good ordinary smoking tobacco can be produced, and if great attention is paid to the selection of the variety, &c., leaf for cigar wrappers even may be produced Tobacco will not stand any wind, and if planted in new land, so as to avoid it as much as possible, we should strongly advise opening up small plots, well-sheltered, and the result should be a very much larger percentage of first quality leaf. In a rich alluvial soil little or no manure will be required, but as the tobacco plant draws from the soil the inorganic matter with which it is rich, if the same soil is to be used again, a large quantity of nitrogenous manure must be supplied; as much as twenty-five tons of well rotted cattle manure is applied in Holland, whereas in Sumatra the land once cropped is abandoned as useless. The best manure to produce a quickly burning leaf of fine aroma is potash, which can be supplied by applying 200lbs. of good saltpetre to the acre. We have before said that should the same land be used again it would be necessary in Ceylon to manure it very heavily indeed (this is not the necessity in America, where the soil is rich in plant food, or in Hungary and Holland), but we imagine that inorganic matter such as potash and lime taken out of the soil might be supplied by planting in rotation. Indian hemp is said to thrive particularly well after tobacco, and no doubt Indian corn, Helianthus or any cereal or pulse is well adapted for cultivation in the course of rotation.

We would impress upon the cultivator, that though he may introduce a fine species direct from Sumatra or Manilla, he must be prepared for deterioration; it is unlikely that the new *habitat* will supply the thinness and silkiness of leaf and the aroma, unless, climate, soil, and especially treatment are identical. Now supposing that the object to be attained is a wrapper leaf, then the leaf must be broad smooth, thin, and elastic, and dried to a golden color, while fine aroma is not indispensable. The variety that most approaches these characteristics is the heart-shaped Maryland tobacco, grown in Germany, and already largely introduced into India. While for a hardy variety the short leafed Maryland tobacco might be introduced, it is a vigorous grower and a good smoking tobacco; but the tobacco that grows commonly and well in tropical countries is the *N. Rustica* growing in Brazil, Turkey, and Asia generally, and furnishing a large leaf, suitable for wrappers, being worth, approximately, 80 cents. a lb. We do not see, however, why with careful cultivation of a small well-sheltered plot, the higher priced tobaccos of Manilla, Cuba, and Havannah should not be cultivated, and made to thrive in the rich soil of the Eastern Province where irrigation is practicable. We purpose devoting a second article to the drying and curing of this product later on.—*Ceylon Times.*

NOTICES TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

CORRESPONDENCE.

CARDAMOMS.

TO THE EDITOR.

SIR,—Having seen an article on the cultivation of cardamoms in your paper of the 1st July, I shall feel obliged if you or any of your readers can inform me where I can procure a book on their cultivation.

[illegible]ugust 1880. MALABAR.

[illegible] We [illegible] Dr. Pereira on the subject of spices, which [illegible] all the information he requires. We have [illegible] the book ourselves, and cannot therefore speak positively.—ED., *I. A.*

SILK.

[illegible] THE EDITOR.

[illegible]—Can you inform me, through the columns of your paper, whether or not the [illegible] cocoon has a marketable value in Calcutta, and [illegible] what is its value per maund?

[illegible]ssam, 7th August 18[illegible] W. [illegible] YOUNG LESLIE.

[illegible] always find a market in [illegible] will get you the present value.—ED., *I. A.*

INFORMATION WANTED.

TO THE EDITOR.

[illegible] A. B. has succeeded in domesticating the silk-worm [illegible] will he kindly send particulars and say if he has any eggs to spare? If any of your readers can give information regarding the winding off of the Eria cocoon, I shall feel extremely obliged. Can they be reeled in the same way as the mulberry feeders?

ONE INTERESTED IN SILK.

PAPER FIBRES.

TO THE EDITOR.

SIR,—Having read in your paper several articles on the matter of obtaining cheap materials for manufacturing paper, I have the pleasure to inform you that I have posted this day to your address a packet which contains two samples of fibres, No. 1 taken from the Lady-finger plant, and No. 2 from branches of Jainti. Both of these plants grow very rapidly, and without any particular care being paid, except to extract the fibres. No other materials could be obtained more cheap than this kind, provided it answer the purposes.

August 1880. B. L. FRIZONI.

N[illegible] We are obliged to our correspondent for the samples which came duly to hand. We shall be happy to show them to any one desirous of inspecting the same.—ED., *I. A.*

PRESENT STATE OF JAMAICA.

TO THE EDITOR.

SIR,—This island is a very fertile one, with rich woodlands and scanty sugarcane fields interspersed everywhere. Its rise depends [illegible] on the sugarcane crop, and, as that plantation has failed, the island looks gloomy, not because a huge cloud overhangs her, or because the sun does not shine, but because there is not much work, no demand for labour, and consequently the place has in three hundred and sixty-five days only ninety brisk ones. The land, notwithstanding the several fictions (that it will not yield after two or three years' plough) is highly fruitful, and to add to its fruitfulness, running streams, springs and ponds are to be met with wherever one turns, so that when much rain does not fall: there is very little of the cry "everything is scorched,"

The disadvantage from which the island is now suffering is not merely from the want of labourers (as is the general rumour) but on account of planters not having sufficient capital to continue on the working of the cane fields. All the old planters have quitted the planting field, and those who have succeeded are inert on account of the prior reason—*viz.*, insufficiency of capital, there fore there is an end to general employment and occupation.

This island which once carried the name of the "great sugar country," is not so now; other places have arisen and she has sunk several steps lower than the rest of the "sugar manufacturing world."

And now the question arises—When shall Jamaica again reach her former zenith? The question may be fairly answered thus:—

1. When planters think again of cultivating those sugarcane fields which have grown with noxious weed and unwieldly wood.
2. When planters know again the value of the products of Jamaica.
3. And when they will plan not only to cultivate sugar and rum, but other products of commerce which will serve to be profitable to them, and of use to those demanding.

Of the many acres of land, not half can be said to be in thorough cultivation, and according to a late report, it is still decreasing on.

Many who have tried to relate of the advantages and disadvantages of this island, say that labourers are required. When this was said before, it conveyed a right meaning; but we may now safely assert that the island is in need of men withstanding, capital, —persevering men, and men who have an adscititious brain than the common majority.

Another cause of this island's failure is party prejudice, but as this exists among the lower classes and the vulgar, who are uneducated, I will not then lay it as a general source of grievance.

Montego Bay, Jamaica, April 25, 1880. CRITIC.

DISEASES OF THE TEA PLANT.

TO THE EDITOR.

SIR,—We read, hear, and see a great deal about the different diseases to which the tea plant is more or less a victim in the various districts where this cultivation has been undertaken, but up to this time no writer has been found to show us clearly the means by which we may be able to keep our plants free from diseases, which in some instances prove fatal.

Some attribute the cause to bad soil, others to pruning, &c.; doubtless the former being one of the chief causes, cannot be disputed. Nevertheless climate too, I dare say, has a share. For instance one may observe that plants on a tea estate at a high elevation are not so much attacked by bug as those lower down. The rapidity with which these little creatures increase in number is marvellous. From the time when first a bush is attacked, the number are so few, that one may almost count them, but note the difference two months later, and you will be surprised; most likely the whole plant is one mass. A little later you may find your plant is no more: it begins with shedding its leaves, and gradually the tree dies out.

Hints from the pen of some scientific man, I dare say, will be of great worth to some who have failed to hit upon means of getting rid of this pest. I have tried lime, tobacco-water, and other things which I thought would be disagreeable to the insect class, but all to no purpose.

A proof of soil being poor, may be somewhat arrived at by the appearance of plants put out on it, which will in the one case show vigour and the other, appear sickly and sluggish in growth, but this may easily be rectified by the attention of the planter being drawn to supplying what is necessary. Much is said regarding chemical or artificial manure, but very few will dispute that ordinary earth manure is as good as any, and, if applied proportionally, will produce the desired results.

I wish here to say a word regarding a disease (I can call it nothing else) which may yet be a stranger in some districts, and as "prevention is better than cure," ere it spreads very far some may, through hints from some scientific writer, be able to check the evil while yet in the bud.

The estate where I first observed, what I am about to point out, is barely four years old.

The soil though not of the very best kind, is to all appearance one that could nourish tea plants for the next twelve years to come without application of manure of any description. I observed till May last the plants looked quite healthy. Since then several have as though commenced to fall back, and a great number seem dying. These appear to commence dying at the branches, beginning at the upper end, till they reach the main stem, and gradually the tree perishes. The space of time I calculate from the first signs of dying to the complete dying out of a plant does not exceed three months. On digging up one of the bushes which perished in this manner, I observed that the roots were slightly covered with a white substance, much like fungus in appearance, or as may be seen on trunks of decayed trees.

It would be a great favour conferred if any of the contributors to your valuable journal would be good enough to give us an insight as to cause and remedy, by which we may be saved a further loss of our tea plants by this disease which is quite a new thing to me, though to men of long experience it may be quite familiar. We can but look to men of sound practical experience to help and enlighten the ignorant and

Neilgherries, 21st July 1880. "IGNORAMUS."

THE FOOD OF CATTLE.

TO THE EDITOR.

SIR,—With respect to several letters that have appeared in the *Agriculturist* on the subject of feeding cattle, I would offer a few remarks, leaving it to those interested to think and act for themselves. In the matter of feeding cattle with either raw or boiled grain, I have seen horned cattle fed with raw gram, a bean called "Moochacotay" in Tamil, in Bengal called "same." This when well soaked, they pounded into a thick pulp in a mortar and gave to the cattle. In this way the cattle must derive more benefit than by simply soaking, and giving the grain entire, because, as one of the writers has acknowledged, the grain is sometimes passed out entire. This method of giving the grain in pulp can only remove one objection, *i e.*, there can be no loss of food from indigestion. But who that has seen grain in its various conditions, will be satisfied with that? If the grain is simply to be soaked, then what becomes of all the worms, and such like, as well as their eggs which both horses and bullocks have to swallow, breed, and in some instances develop into other stages of existence, and which meantime go on drawing all the nourishment required for their existence at the expense of the health as well as the life of the animal they are breeding in and living on? If boiling is really objectionable, then *broil* well; the gram may then be given in that state or soaked. By this means, about one-half, or less, fuel will be required, and all vermin will be destroyed, the grain meantime becoming more palatable and easier of digestion. Your Seringapatam correspondent's letter contains these words:—"But it is the belief amongst the native that this would produce colic, inflammation of the bowels," &c. I will just give one instance from my own observation to prove the soundness of the native views. During the late famine in Madras, as horse gram (*coolty*) had become very scarce residents in those parts bought the Bengal gram (*chenna*), soaked it and gave it to their horses. A friend complained that "not only were people of all classes suffering in various ways, but horses too; and I was assured that both the horses of the house in question had been totally unfit for work for some time, as shortly after their feed their belly would swell, and they would lie and roll and groan as if in great pain. I learned during the day that these horses had the Bengal gram *soaked* and given them, and I at once advised the boiling of the gram, when to the astonishment of all, the horses became perfectly well, and fit for work: there was *no more soaked gram.* The cause in this case no doubt lay in the germ which heat neutralised. Not a particle of the strength of boiled gram need be lost to cattle. Cool the water that is strained from the boiling, and give it to the horse to drink. If the horse won't drink it that way, pour it into a tub to ferment, then with the addition of his usual allowance of water give it to him. He will certainly drink with a relish in its sub-acid state. To this add the water that rice is washed with in the first instance, before boiling, as well as the water strained from the rice after it is boiled—this in hot weather will be drunk with great relish by all cattle. In the days of yore, say sixty years ago, ship captains in Madras paid *one double fanam* ($2\frac{1}{2}$ of an anna) for the full of a quart-pot, a couple of green chillies being cut up in it as a zest. But there is another item of diet for the horse that must not be lost sight of, *viz.*, grass. How is this got? A woman or man digs it up, roots and all, with a kind of hoe, consequently it has to be washed, to free it from the clay, &c. During the rains there may be plenty of clean water handy, but in the dry season water is not only scarce, but what little there may be is often in the filthiest condition, and quite alive with animalcul'æ, &c. Into these sinks the grass is thrown to get rid of the earth, and there it is often allowed to lie, to enable it to get a fresh appearance. Is it not likely that in those stinking cesspools the grass gets filled with animalculæ, worms, &c., and is it not from this that the horse gets all the ringworm, sores, and itch he may be attacked with? Let your readers think on this and insist on grass being brought to them without being washed outside in the fields or villages; let it be washed at the house or stable with well water. I recollect seeing a buffaloe killed as an offering to "Mariatha" during cholera time; the stomach was full of the grass it had eaten, and in it there

was an immense amount of small leeches, which were all of a pale pink colour and alive. If the animal had the power of digesting these, well and good, but if they had the power of adhering to its intestines, then what wonder at the great mortality that often carries our cattle off by scores, while all directly interested, wonder why, and never know.

Now if it is a fact that gram becomes "heaty" if boiled, the remedy is within the easy reach of all. To a measure of wheat or fine rice bran, add one desert spoon of nitre (saltpetre), finely powdered, and about a tumbler of treacle that has been well boiled, give this once a week during the hot season, to your horse; it will cool his blood: I know this to be given, and with good result.

Give your horse, occasionally, some ripe plantains of the large coarse kind, slices of ripe pumpkin and water-melon, all of which are cheap and plentiful in most parts of India.

Take a real interest in your cattle, look at all that is given to them, see that all is clean and wholesome, and put a proper quantity of salt in their food. Sometimes give good, clean treacle; let this be well boiled and kept corked in bottles; it will do more good than the bare insipid gram and other grain, without the least particle of anything to make it palatable.

The health of our cattle depends often on the care bestowed on them, let us do our duty to them, as they minister not only to our wants, but to our comfort; and let us always bear in mind that the righteous man is merciful to his beast.

Those who give cotton-seed to milch cows, should make sure that the seed is fresh and sweet; old and rancid seed is only fit for manure.

12th August 1880. OBSERVER.

TEOSINTE A MEXICAN FODDER GRASS.

(To the Editor of the Ceylon Times.)

SIR,—I am surprised that no one has recorded their experience of the Teosinte fodder grass. The prickly comfrey was decidedly a failure —not to say a swindle. Of course it is a fodder for cattle and so are turnips and cabbages. It can be made to grow luxuriantly by garden cultivation, but it "won't pay." The Mexican grass is certainly a paying thing to grow, for while in guinea grass the thick stalks are unpalatable to cattle, the Teosinte has an advantage, *viz.*, that the thick stalks no matter how thick, are devoured by horses, cattle, and pigs, owing to the saccharine matter they contain, the manure would not only be superior, but the beasts themselves must fatten. There are certain places where Guinea or any grass won't grow. It is not expected that Teosinte can flourish on such soils. As a rule instead of a bad piece of ground being turned into a grass field, I would advise a small portion of really good ground to be selected for any kind of fodder grass. A little trouble in loosening the soil occasionally and replanting after breaking up the old clumps and clods, a little expenditure on artificial manure to be applied at the rate of 10 per acre including labour, will go far to give an immense quantity of substantial fodder making rich manure. The proportion in weight is as nearly three of Teosinte to one of Guinea grass, judging from the result obtained from a small plot of each grass treated equally. The quantity remaining in stalls of Guinea grass after feeding cattle when weighed, shewed 27 per cent. unconsumed, of the Teosinte only 11 per cent. To those who take an interest in a fair number of cattle and look to improvement in the stock, and to a good supply of rich manure, with but a small porportion of troublesome long stalks to impede the turning over and heaping or removing the manure. I strongly advise the planting of the Teosinte. It grows well on banks of roads and drains, and luxuriates in ravines. Its habit is not unlike the Indian corn these are the male and female flowers. The grass should not as a rule be allowed to run to seed. The rapidity with which it grows after each cropping is simply extraordinary, and from a single stool raised from one seed, as many as 17 perfect stems have been got by mere cropping. Length of average blade is 3 feet 9 inches, but many a foot more; general width in centre 2 to 2½ inches. Mind I speak of grass well attended to. I had read and heard of the grass, but never cared to experiment until in Galle a ship captain who had been to Mexico and knew the grass, confirmed the accounts given of it. He spoke also of two other good prarie grasses which he thought would suit the low-country marshes.

L. T.

FORESTS AND RAINFALL.

(To the Editor of the Bombay Gazette.)

SIR,—Anent the subject of forests and rainfall, I would remark that the pretentions of forest conservators remind me of nothing more vividly than the claims of the African priest and medicine man. To quote a popular work:—

"The African priest and the medicine man is one and the same, and his chief function is to make the clouds give out rain. The prepartions for this purpose are various—charcoal made of burned bats; internal parts of animals, as lion's hearts and hairy calculi from the bowels of old cows; serpents' skins, and vertebræ, and every kind of tuber, bulb, root, and plant to be found in the country;" in short, all "forest produce." Although you disbelieve their efficacy in charming the clouds to pour out their refreshing treasures yet, conscious that civility is useful everywhere, you kindly state that you think they are mistaken as to their power; the rain doctor selects a particular bulbous root, pounds it, and administers a cold infusion to a sheep, which in five minutes afterwards expires in convulsions. Part of the same bulb is converted into smoke, and ascends towards the sky; rain falls in a day or two! The inference is obvious!"

So also is it with the forests and rainfall! The thing is quite plain. The rain tree must induce rain, and the Jovian functions of forests conservators and their assistants are beyond all proof and question. Some things are above reason!

JUPITER PLUVIUS.

THE COFFEE BORER.

(To the Editor South of India Observer.)

SIR,—In your issue of the 31st July, there is a local para. referring to the ravages of the "borer" in the Nellacotta to the district. It has been very generally remarked here, by all who have seen the para. in question that it is calculated to convey the impression that some of the estates in the district are suffering from exceptionally severe attacks of this insect. This is by no means the case. The facts are rather that there is less "borer" this season, on the whole, than there has been for years past. Every season we have borer, more or less, but during my six years' experience in the district, I have never known any estate to have suffered from an expectionally severe attack. As is the rule in the Ouchterlony Valley, so here, the trees attacked are regularly and systematically cut dowh and burnt at this season of the year. If the insect does make an invidious distinction in the trees it selects to attack, I should certainly say from my experience that weak and indifferent trees very generally appear to bear the honor of the distinction, and not so much the best trees, as stated in your para.

NELLACOTTA PLANTER.

A NEW VEGETABLE.

(To the Editor of the Ceylon Times.)

SIR,—As you are paying a good deal of attention to new products, perhaps you will allow me to call your attention to the following account of what is termed in home papers "a new vegetable," and to ask if it has been grown in this island. It is the *Soja hispida*, a species of leguminous plant, somewhat resembling in habit and appearance the well-known pea. Unlike the latter, however, it has two distinct uses—industrial as well as alimentary. It is highly prized in China and Japan, and is said, indeed, to take its scientific title from the Japanese name of a sauce-sooja—which is made from its seeds. The seeds are very similar to a "marrow-fat" pea, but contain a large quantity of oil, which is either pressed out of them or boiled out in process of cooking the seeds for the table which is effected by simply throwing them into boiling water, when the outer skin bursts and floats to the surface, together with a quantity of oil, both the oil and the husks being skimmed off together. These may be either used as cattle food, or the oil may be separated and employed for various purposes, while the husks are still valuable as a feeding stuff or as a manure. The peas are boiled for about twenty minutes, and furnish a dish which is highly relished, not only by the Celestials, but by many Europeans who have tasted it. It is said to resemble in flavour the green pea, but lacks its sweet taste. The boiled sofa is also prepared as a cake and as a sauce, being fermented for the latter purpose, and salt, pepper, &c, being added. The sauce has a high reputation among the Chinese and Japanese, not only as a condiment, but as a medical agent.

The plant is described as thriving in very poor thin soil, and as adapting itself to a variety of climates. In Ceylon we are most deficient in the matter of vegetables for culinary purposes, and this would, from the account given of it, appear to be well suited for us and easily grown.

THE WILD VINE OF CALIFORNIA.

(To the Editor of the Englishman.)

SIR,—I have just brought from San Francisco a small parcel of seeds of the wild vine of California (*Vitis Californica*), which I shall gladly distribute to persons desirous of having them, and who may be able to put them out in suitable localities.

The California vine is now very much valued in Europe, and if these seeds should be successfully grown in India, they might be the initiation of an important and valuable industry, either for making wines or raisins.

Will you please make this known in your paper and oblige—

JOHN MARTIN.

5, Garstin's-place, August 14, 1880.

WHITE ANTS.

(*To the Editor of the Times of India.*)

Sir,—Your Ahmedabad correspondent "Hortus" calls for a cure for a disease which does not exist. It has been proved scientifically that white ants will not eat any vegetable with vitality. I would, therefore, suggest that Hortus should look to his *malee's* **method of planting or weeding, for I find if a rose-tree gets a knock with a** *khurpee* **or other tool injuring the bark, it admits water and causes death, when the white ants immediately seize it, the top remaining fresh and green for some days. Probably the** *malee* **detects, or you yourself notice, that the tree is looking sickly, and the roots are then examined for the first time, but the white ants may have found it out long before.**

The Indian Agriculturist.

CALCUTTA, SEPTEMBER 1, 1880.

THE BENGAL RENT LAW COMMISSION.

WE expected a good deal from the Commission appointed to draft a revised rent law. The experience of Mr. Dampier, the industry and legal lore of Mr. Field, the talent of Mr. Mackenzie, and the critical acumen of Mr. Harrison, with Mr. O'Kinealy's zeal for the improvement of the condition of the cultivators, could scarcely have failed to produce much when applied to a subject so important as the reform of our land system. And the report which the Commission has sent in fully justifies the hopes which had been entertained. Taken as a piece of literary and legislative work it is the best of its kind, as far as our experience of such productions in India extends. The Digest, which is its basis, gives a complete statement of the law as it stands, incorporating all changes, additions, and explanations by which the decisions of the High Court have supplemented the regulations and laws passed in Council. Sir Richard Garth has pronounced this work excellent, so that there is the best authority for assuming that the labours of the Commission rested on the only solid foundation,—a thorough knowledge of the laws which it is desirable to amend. The draft Bill now submitted goes over the whole ground to be covered; it is clear, logical, and exhaustive. The report by which it is prefaced gives in forcible language the reason for every change which it is proposed to make. We may say that the light of day has for the first time been let in upon the subject, that it has been treated in such a manner that any statesman or student, whether in another province or in England, can master it without the aid of local knowledge. On the question itself it is vain to look for any general agreement; in India, as in every other country, there is a landlord's party and a tenants party, and the two can never agree when the measure under discussion is really important; but we believe that all will be glad to acknowledge the utility of a work which ensures that the legislature, in whatever direction it moves, will have the guidance of light and reason.

The Commission has made several proposals most favourable to tenant-right, and which certainly should meet with our approval, as we have long advocated them. It is a defect in the present law that, while careful of the rights of privileged ryots, it has no provisions whatever for the protection of the ordinary tenants who form a moiety of the whole, and are becoming a majority. The landlord may rack-rent them or eject them at pleasure, or may appropriate without payment such improvements as they have made, such as the trees planted and reared, the wells sunk, the enclosures formed. It has even been decided in a recent case that a landlord thus evicting may take the standing crop, however valuable, and however near maturity. With regard to these unprivileged ryots, the Commissioners have remembered that, as a Trinity man at Cambridge is said to have charitably remarked of the undergraduates of the smaller colleges, "these, too, are our fellow-creatures." Ryots who have been in possession for three years are declared to be entitled, on ejectment for some cause other than an arrear of rent, to compensation for improvements effected by them. They can also get one year's rent as compensation for disturbance. In Ireland, from which the phrase and the thing is borrowed, compensation for disturbance may amount to five years' rent, so that it appears that the Commissioners can move in the direction of tenant-right only at one-fifth the pace of Mr. Gladstone's mighty strides. The compensation for improvements, too, is not assigned as freely as in the Act of 1870. Moreover, it is not clear why a tenant so unfortunate as to be ejected before he has been three years in possession, is to get no compensation for the improvements from which he cannot have as yet derived benefit. It would have been better had the proposal of Mr. Mackenzie, supported by Mr. O'Kinealy and Baboo Rajendro Kumar Seal, been adopted, and the three years' ryots raised at once to the privileged class, in which case their proposed status might have been inherited by the residuum, the unfortunate tenants left unprotected because they have not held for three years. But we must say that, voting in January, before the recent change of Government, the Commissioners went as far as could, at that time, have been expected. It is of little use to propose measures which, with reference to the known views of those who from above control our policy, are sure to be rejected. The Commissioners did as much for the ryot as was possible at the time; when Sir Ashley Eden meets his Legislature next season, he will be in a position to go much further, and really to settle the question.

On the occupancy or privileged ryots it is proposed to bestow this further right, that their holdings shall be alienable. At present such holdings may be sold or not according to custom, and it is always difficult to find out what the custom is in a particular place. There are some who believe that if ryots are given the right to sell, they will dispose of at once their tenures to the money-lenders; but this view, though plausible, is not borne out by experience. At present there are at least a hundred thousand alienable tenures in Bengal, from those of the peasant taluqdars of Chittagong on the south-eastern frontier, to the Surbarahars and privileged ryots of Orissa on the south, and the Gurjashtadars of Shahabad on the west. These are bought by money-lenders only occasionally, and the class connected with them shows no tendency to die out. The idea of declaring all occupancy right saleable is, as far as we know, Sir Ashley Eden's own, and it strikes us as being what *Punch* calls a happy thought. Nothing gives the proprietory feeling but the power to sell, and it is to the pride of proprietorship that we must look to to urge the ryot to improve. In fact it may be said, as a general rule, that all ryots with alienable tenures are now well off, and no others, except where population is thin. If the bulk of the ryots are given this privilege, there is room for a reasonable hope that they may become prosperous.

Since Sir Ashley Eden took the reins we have heard less of the wild schemes for unlimited enhancement of rent on new principles, which Sir Richard Temple declared that he would have invented. Baboo Kristo Das Pal heads a party which openly aims at depriving the occupancy ryots as a body of the statutory privileges they at present enjoy as to fixed rent rates, giving them in exchange other privileges of less value. He nearly succeeded in carrying out his purpose in Sir Richard Temple's time, procuring the introduction of a Bill which, if passed, and maintained, would have led first to an agrarian insurrection, and then to the general impoverishment of the cultivators. We are glad to see that the Commissioners have given no encouragement to these wild and pernicious views, and that even the native members who represented the landlords' interests, did not put them forward. The occupancy ryots under the draft Bill retain their right to hold at the old rates, subject to enhancement only on the old grounds. They are further protected against rack-renting by some new precautions. Enhancement can take place only once in ten

years, and in certain cases it cannot be carried to so great an extent that the rent shall be more than doubled, and in no case shall the new rate be more than equal to the value of one-fourth of the staple crop. It may, moreover, be made by instalments.

The equivalent given to zemindars for the curtailment of their powers involved in the extension of tenant right, is the power to put in motion the revenue machinery of Government for the purpose of raising rent rates, as far as the law permits that they should be raised. The landlords complain that they cannot enhance their rents through the Civil Courts, the process being too clumsy and expensive. They are to be given the use of the agency with which Government effects its own settlements, and which may be supposed to be the most suitable which experience can suggest. This is undoubtedly a great boon to the landlords, and a great injury to the tenants. We, however, doubt whether it will please the shrieking brotherhoods of the Associations, which have got up the agitation for new means of enhancement. These are formed by the more powerful, active, and pushing landlords, who have already enhanced by what they are pleased to call the consent of their ryots to rates beyond those to which they are entitled under the substantive law, and no change which merely gives increased facilities for enforcing existing powers will be of any use to them. What they want is either that the ryots shall be deprived of their present substantive rights, as by Sir Richard Temple's Bill, or that their own hands may be strengthened for the purpose of extorting further "voluntary" enhancements, as by the late Bill, to enable Judges to refuse to hear witnesses for the defence in rent cases. The concession now given will be of use only to the quiet and moderate landlords, who remain in the background, and have no influence in the press or at public meetings, the organs of public opinion.

We may, therefore, expect, indeed we have already witnessed, a strong opposition to the Bill from the party headed by Baboo Kristo Das Pal, the only native influence which is a real power in the country. Sir Ashley Eden's personal connection with many of the leaders of this combination may do something to soften their hostility, but, as we apprehend, not much, their disappointment at the result of the agitation which, since the movement of the ryots of Pubna in 1874 to maintain and assert their position under the present law, has been carried on to change that law to the detriment of the ryots, will be too great. And the question arises, if the opposition of the zemindars must be encountered in any case, why make concessions to it which will not satisfy or mitigate it? If we are to have a tenant right measure, why not make it effectual, and therefore final? Why not dispose of the matter once and for all, as Stein did in Germany? The draft Bill, excellent as it is when compared with other measures recently introduced in the Indian and Bengal Legislative Councils, stops far short of this. For instance, it permits the landlord to contract himself out of all his obligations under the Bill. Now tenant right can never be permanently defended where such a breach for attack is left as this. It is the rift within the lute that maketh all the music mute. The Conservatives knew this, when, in passing a law to give compensation for improvements in England, without intending that the right to receive such should be effectual, they provided that the rule should not over-ride any contract. Mr. Gladstone knew it when, in 1870, he enacted that any contract between Irish landlords and tenants, purporting to exempt the former from obligations under the Act should be null and void. Under the Bill of the Commissioners, a zemindar may keep all his ryots tenants-at-will at rack-rent rates, if he only takes sufficient trouble. He can do this either by registered agreements, or by making them change their fields every three years, on the system which Sir Richard Garth states has been adopted for that purpose by landholders in the Central Provinces. The principle in Bengal should be that, as the revenue is moderate, so should the rent be also; and this rule should be made so strong and close, that the most powerful landlord should be unable to break through it or the most cunning to creep under it. [illegible] such a policy, Bengal must in the end be ruined by rack-renting, like Behar and Oudh. It would have been useless to have asked for a law of this kind a year ago, but now the hour has come, and we hope that Sir Ashley Eden will prove to be the man.

IRRIGATION IN SINDH.

IRRIGATION in Sindh is a subject of more than ordinary interest, as being attended by unique conditions. Elsewhere (except in some parts of the Punjab) irrigation is more or less of a luxury; in Sindh it is a necessity. The extension of civilisation in that region is commensurate with the water spread of the canals. These, of course, are all fed from the Indus; and indeed that river might claim honours not inferior to those of the Nile, if practical benefit were the test, apart from historical and traditional glories. Like the Nile, the river of Sindh flows through a rainless country, and swells mysteriously when the drought is greatest. Its floods are more widely used than those of Egypt; the cultivator does not merely scatter his seed as the waters retire, but tills fields far removed from the river by the help of long canals. The system of Indus Canals counts up no less than 5,643 miles, and waters more than two million acres, or about 3,200 square miles. To this area must be added the aggregate area of the tracts directly submerged by the annual floods, it is not shown in the canal returns, but may be assumed at about half as much again, making a total of some 5,000 square miles redeemed from the desert by the bounty of the river. Sometimes the river fails in its ministrations; more frequently it overdoes them, sending down a volume of water that sweeps away embankments and bursts the canals. Such was the case in 1878-79, when the Kusmore embankment above Shikarpore was breached, and the floods joining their waters with those hastily contributed by the hill streams from the west, the gift of a sudden shower, swept over the whole country from Kusmore down to Sehwan. Repaired and strengthened, the Kusmore dam stood against the inundation of 1879-80; but a few weeks ago, it was breached again. These floods do great damage to the autumn crops, which are destroyed by submersion; but some compensation is got in the spring, when wheat and oil-seeds can be sown over a larger area than usual. Wheat, indeed, depends almost wholly on direct flooding, as distinguished from canal irrigation. The latter suffices to water the autumn crops while the canals are full, but when the river shrinks into its normal dimensions, the canals run dry, and there is usually no water left for cultivation in the spring. Exceptions are found in some favoured places, where the canal supply, besides irrigating the autumn fields, yields a surplus which can be stored in reservoirs or water-holes for use several months later, so that a crop of wheat can succeed one of rice or millet. Generally, however, canal-watered lands produce only autumn crops, and lands watered by floods give only the products of the cold months—wheat, oil-seeds, and pulses for the most part. Great uncertainty attends cultivation of this kind. If the floods come in short measure, the area sown is deficient; if they are excessive, it is an advantage to have a large area for sowing, on the condition that it can be sown in time; but often the waters refuse to recede till the season is past. The ideal floods, so far as wheat cultivation is concerned, would be those which should submerge the greatest possible area, and recede with the greatest possible rapidity. The character and extent of the inundation vary greatly from year to year; but on the whole years of flood are commoner and less harmful than years of drought. The year 1878-79 produced the highest inundation, yet recorded, and as a consequence, floods of a magnitude unknown since 1826; nevertheless, irrigation prospered, and the official report on Sindh Canals has little to chronicle but success.

Capital accounts are not kept up for all the canals, but the returns given show that a capital expenditure of 81½ lakhs on certain lines brought in a net return of 2,40,000 rupees; that is to say, about 3 per cent. This return, however, ought to have been about 5 per cent., had revenue been fully levied from the canals in the frontier districts and Khelat territory. These are two works bearing the ominous names of the Desert and the Forced Labour (Begari) canal; and the [illegible] dues on the lands they water seem to be the same

as those which prevailed generally throughout Sindh until recent years, but never worked satisfactorily. The desert landholder is assessed to water at 10 annas 8 pie per acre, on the entire area of his holding; and he is supposed to cultivate one-third of this area annually, so as to effect a proper rotation of fallows; thus the rate per acre of cultivation would be two rupees. What he actually does, is to water the entire holding whenever he can get water enough, and then to cultivate it all, whether with autumn crops, or, if the water lasts, with wheat and other spring grains. In this way he gets off with one-third of the proper assessment per cultivated acre. Of course he loses his chance of fallowing the land, but that gives him little concern, for waste land is plenty, and he has only to throw up his whole holding when the year is out, and take up another of equal size. In Sindh Proper, this plan of cheating the revenue has been stopped by requiring the landholder to pay at full rates for the whole of his holding, whether cultivated or not; while the areas of holdings are at the same time restricted to what can fairly be brought under the plough in an average season, and fallowing is provided for by allowing the holder to relinquish fields successively, retaining a lien on them for two years after relinquishment. Some such arrangement will probably be introduced into the frontier districts sooner or later. Meanwhile, if the revenue returns for 1878-79 be examined, the productions of irrigation in Sindh will be found such as to satisfy the most exacting critic. The expenditure on maintenance and collection was 16½ lakhs; the revenue realised on account of canals was 29½ lakhs. But in truth, from the revenue officer's point of view, the virtue of the canals is inestimable; for without them there would be no revenue from these lands at all. The whole area of Sindh is about 34,000 square miles, only 13,000 of which are recorded as culturable, and about one-fourth of this latter area is, as we have seen, under canals. These figures convey a graphic idea of the desert and sterile character of the region; yet the lands recorded as unculturable owe their unenviable distinction simply to the fact that they lie above the level of the canals; and it may be found possible, in the long course of years, as the canals extend and trees are planted, to bring even these high levels under cultivation, by attracting rainfall as a consequence of afforestation. At present along a single canal (that of Forced Labour) the Canal Department can point to nine thousand trees planted by the waterside, eight thousand of which are *babul*, a tree very suitable to a country which has been called Little Arabia, for the *babul* is the very acacia which in the greater Arabia waves her yellow hair

> Lonely and sweet: nor loved the less
> For flowering in the wilderness.

But the yellow hair of the Indian *babul* waves unnoticed, save haply by some solitary Englishman riding home through the thorny jungle in a golden afternoon of March, when the air is heavy with faint perfume.

Sindh is in several respects one of the most remarkable provinces of India, and not least so with regard to irrigation. Nowhere else do we find an entire province dependent upon a periodical water-supply, and nowhere else are canals so emphatically productive works. The annual Canal Report for Sindh furnishes the most striking testimony to the benefits of a strong and upright Government, however far removed by alien blood and creed, from sympathy with the people, under its rule. Native governors designed some of the most important works, but it is only British supremacy that can guarantee their continuance. Persia, Mesopotamia, parts of Arabia can offer examples of the fate of embankments and canals under the vicissitudes of Oriental despotism. A great monarch accomplishes a gigantic work; and his successors allow it to go to ruin; while the people, disheartened and pillaged, have neither the energy nor the means to do the repairs themselves. Even in Sindh, the annual clearances, so necessary to the efficiency of the canals, are not managed without some trouble. An inundation canal differs from a permanent canal in the circumstance that it receives flood water only, which cannot be turned on and shut off at pleasure. Stones and silt come down with the flood; the volume of water cannot be regulated at discretion, and often breaks away from control altogether, striking out new channels and leaving the old one almost undistinguishable. Another tendency of flood irrigation is to convert the canal into a river, and thereby destroy its utility as a channel for the economical distribution of water. Even in the best years, the work of clearance is no light one, and but for the steady pressure of the canal officers, it would be very imperfectly done. Here it is that the regularity and persistence of a civilised administration prove so useful. Much depends, too, upon the careful collation of statistics, shewing how irrigation stands from year to year. Greater accuracy in these returns of areas is expected as the revised land-revenue settlements are gradually introduced. At present, the estimates of irrigated area are to a certain extent approximate. In the settled taluqas, the data of calculation are the known areas of the 'survey fields' into which the land has been divided for settlement purposes. These fields, however, are often very large (some of them, in the earlier settlements, were as large as 60 acres), and the whole of a field may not be watered; so that in fact the irrigated area has to be estimated by a rough comparison between the known area of the field and the apparent proportion borne to that area by the portion irrigated. In the unsettled taluqas, which are found chiefly in the Hyderabad district, where irrigation is by the Persian wheel, the area is calculated by allowing an average number of acres to each wheel actually in work; while the area of flow irrigation is roughly measured each year. With the revised settlements, more manageable 'survey fields' will come into use, and the cases will be rare where any part of a field has to be left unwatered; thus the area of irrigation will be known with much more precision than at present. There is every reason to believe that it will go on steadily increasing. Sindh is a province which has a future before it. The opening of the Suez Canal has invested the Sindh canals with a new importance; and the wheat growers of Kurrachee now enjoy the advantage of greater proximity to the European market than their rivals in the broad valley of the Ganges or the rich uplands of Chuttisgarh. Nor is Kurrachee alone in this favoured position. Thanks to the railway, which now traverses the length of the province, the remotest taluqas of Shikarpore are but little behind-hand; and Sindh officers may well be excused for the peculiar pride with which they profess their belief in the development of a province which has been redeemed from the desert not less laboriously than Holland from the sea.

UNANIMITY AMONGST TEA PLANTERS.

THE recent meeting of planters in Cachar has illustrated an important phase in connection with the tea industry, and that is—the utter want of unanimity that exists among the planters, as to their wants from a legislative point of view. We remember—several years ago, the Government asked the tea interest to meet and help in compiling such regulations as should be calculated to give the greatest satisfaction in working, and an influential commission of officials was deputed to meet with these delegates. What was the result, why nothing, no two of them agreed on any point, and the only conclusion the Government could possibly arrive at was, that it would be time enough to redress grievances when the aggrieved should decide on what constituted their grievances. For years the friends of the planters have urged union among them, but it has all been in vain. Petty jealousies and local interests have interfered; for it is absurd to say that indifference is the cause, the planter is sufficiently active in airing his own personal grievances. The real cause is that what suits one planter, does not perhaps suit another, and, as each clings pertinaciously to his own idea of what is wanted in the way of legislation, nothing can be done. It is absurd to blame the local Government, which doubtless would so legislate that all parties would be satisfied, if that were possibility. But as there seems no chance of unanimity, what can the Government do? The new society at home, the *Indian Tea Districts Association*, has petitioned the Government for sundry alterations in the existing law, reforms the memorial calls them, and among these that urgently wanted improvement, the propriety of substituting a five years' agreement for the present three years' engagement, occupies a prominent place. Recently a meeting was held in the sudder station of Cachar for the purpose of emphasis

ing this memorial, with the result of as usual agreeing to nothing. The motion for supporting the movement for a five years' engagement as against one for three, was lost, and that by the casting vote of the Chairman.

This must tend materially to weaken the hands of the Association at home, and make them ridiculous in the eyes of the Government. Here they have been most earnestly urging a reform for the planters, which a large section of those planters have just declared they do not want. If the tea industry is to be relieved from oppressive legislation, the first step towards this enfranchisement will be the formulating of the objections to the present Act (VII. of 1873, B.C.,) and submitting a list of such amendments as are calculated to put matters on a fair and just footing. There is no one who knows anything of the tendency and working of that Act, but knows that it bears with undue severity on the planter; we shall simply indicate one or two points in proof of this. In the early days of tea-planting in India, when coolies were imported from their homes and set down in the midst of dense jungles, there existed room for such a regulation as that regarding the maximum price of rice, which was often only obtainable at famine rates. Gardens were frequently situated in isolated spots, far away from bazaars or centres of supply, and were often separated from those centres by long stretches of almost impassable roads, not unfrequently by immense distances without any trace of a road at all. Under these circumstances it was but fair to throw the onus of providing food for these ignorant strangers on the planter, and the fixing of a maximum rate, although not exactly in accord with the principles of free trade, was unavoidable. Now, however, everything is changed, the coolie can always command a supply of grain at ordinary bazaar rates, and if it be considered necessary to keep to the rule of making the planter supply rice at a fixed maximum rate, it would only be fair to make that rate fixed, whatever the price of rice. As matters stand at present, whenever rice goes above the maximum price, the coolie demands his thirty seers per month at the Government fixed price, but should prices fall below that limit, the coolie goes to the bazaar and buys in open market. This we hold to be unfair in principle. The planter loses heavily on rice, and he should be allowed the opportunity of squaring his account, when the price of rice is in his favour. If it be considered advisable to adhere to this idea, it should be so modified that the coolie should be bound to purchase from his employer all the year round at the maximum rate. A much fairer plan would be to assess the average loss to the coolie on this article of consumption, and add that, in monthly increments, to his wages, leaving him all the year round to make his own arrangements as to purchasing. The bazaar is usually close at hand, and there is now no difficulty in procuring supplies within easy distance of each factory. For his own benefit the planter might be depended on to see that the local bazaar was sufficiently close to be convenient to his labourers. This has long been a steady grievance, and one upon whose merits no difference of opinion exists. Another hardship is the ease with which a coolie can break his agreement; although the planter feels this sore to be a severe and costly one, his sense of fair play impels him to do justice to the labourer. He knows for instance, that the coolie may have cost him one hundred rupees to land on the garden, but he also knows that this sum did not go to the coolie's pocket. The whole system of recruiting wants remodelling, but it might perhaps be the quietest plan were the planter to allow this grievance to right itself, which it is doing steadily and surely by the help of improved communication between the recruiting districts and the gardens. The planter must, however, lay it to heart—and this brings us back to the subject we started with—that no satisfactory redress of this grievance or of any other, will ever be attainable until a network of associations is spread over the tea districts, each one independent locally, but all affiliated to some centre, and all bent on carrying out the same rules, which shall have for their object the general good of the industry and not the furthering of private interests. Then a coolie who breaks his agreement without just cause, will have his descriptive roll sent to each garden, and will find it utterly impossible to obtain employment. He will thus be compelled to go back to the planter who imported him at great cost, and with whom he entered into an agreement for a term of years. A few experiences of this sort will put a stop to deserting voluntarily, or with the help of the sections of Act VII. We need not enlarge on this subject, as we imagine we have said enough to point the moral of unanimity and union.

THE SALARU FARM.

THE report on the Government Farm of Salaru for the half-year ending 30th April 1880, has recently been issued, and if nothing else has been effected, a clear proof of the benefit of deep ploughing has been adduced. But we do not get all the information we should like, and which is necessary to enable us to form a clear opinion on the point. For instance, we are not told how the ordinary country cattle managed to drag the English ploughs, nor is a word said as to the relative depths of the furrows as compared with those of the ordinary country *hal*. The experiment referred to was made with *bajri* and cotton. The field selected for the *bajri* experiment, was one overrun with a perennial grass crop, and while this was naturally against a good yield of grain under ordinary circumstances, it served the more clearly to prove the value of the work done by the English plough. The great difference between the English and native ploughs is that the former gives a deeper furrow, and besides it does what is never attempted by the native implement—it completely inverts the mould. Two advantages accrue from this—a new stratum is exposed to atmospheric influences, and the roots of perennial grasses and weeds are exposed to the action of the sun. Thorough exposure to the atmosphere constitutes the best manure the farmer has at his command, and it is one which after all does not cost much. Instead of ploughing so many beegahs per day, according to the cattle power at his command, if the rayat would only do, say two-thirds as much, and do it deeper, he would be astonished at the result. The country plough scratches the soil, and exposes the roots of the weeds to atmospheric influences thus fostering their growth in a remarkable degrees, while the stratum of soil which he actually loosens and leaves to a certain extent to be acted on by the air, is the same stratum which has done duty in this way for centuries, and which has as little humus in it as a handful of sand. With regard to the grass and weeds, the mould board of ploughs on the English system completely inverts the soil and exposes the roots inverted to the influence of the sun, which speedily deprives them of their germinating power. The plough used at the Salaru Farm was a Howard's English, and must of course have been of very light draught, turning over the soil to the depth of perhaps 3½ to 4 inches. We should have liked definite information on these points, and also as to whether the draught was within the reach of the ordinary country bullocks, without having to increase the number of cattle yoked to the plough. In the case of the crop of *bajri*, the result was so satisfactory as to be decisive.

The following table will give at a glance the results.—

	Scinde plough.	English plough.	Excess of English plough over Scinde plough.	
	lbs.	lbs.	lbs.	Percentage.
Grain ...	1,059	1,578	519	49
Straw ...	3,215	4,439	1,224	38

Otherwise than in the matter of ploughing, both plots were treated exactly alike, both having received two artificial waterings.

Now we turn to the cotton. Two acres were ploughed with the English plough, and five acres with the ordinary village implement. In other respects the plots were treated exactly alike, and the results obtained were as follows (in lb. of uncleaned cotton per acre.)

	Scinde plough.	English plough.	Excess of English plough over Scinde plough.	
	lbs	lbs.	lbs.	Percentage.
Uncleaned ...	1,164	1,564	400	34½
Equal to cleaned	388	521	138	31½

The value of the excess 133lbs., was Rs. 28-10-4, it having actually sold for this sum, while the cost of the extra deep ploughing was Rs. 5-5-7, leaving a clear gain of Rs. 22-4-9 per acre. And this is not all. The improvement resulting from the deep ploughing will be found to be permanent, and future crops will derive benefit from it. In this way the value of the land will be improved.

During the half-year under notice, sundry other experiments were entered on, but as they do not seem to have been followed up carefully, they were bare of useful results. For instance, in one case, village cattle were permitted to destroy a crop, and surely where the exact results of experiments are aimed at, such a contretemps should have been prevented. The experiments with different manures gave much less of a valuable residue of results than did the deep ploughing trial, and we would strongly urge on cultivators, both of cereals and perennial crops, such as teas, coffee, &c., to give a large amount of attention to deep cultivation, where of course the soil is suitable. Where the subsoil is cold and sour, it would be ruinous to bring it up to the surface, but where there is a fairly good subsoil, as is the case in most cereal soils and in almost all tea soils, the advantages of deep ploughing and hoeing cannot be overrated.

EDITORIAL NOTES.

With the view of promoting agricultural improvement in Bengal, and encouraging the study of scientific agriculture, the Lieutenant-Governor has determined to create annually two special scholarships of £200 a year each, to be held by science graduates of the Calcutta University at the Royal Agricultural College, Cirencester. The first two scholarships will be tenable for two and-a-half years from the commencement of the January term in 1881. Only natives of Bengal, Behar, or Orissa, who have passed the B.A. examination on the Physical side, will be eligible. An allowance of Rs. 1,000 will be made to defray the expenses of each scholarship-holder in proceeding to England, and a similar allowance will be made for the return journey on the completion of the course. Applications will be received by the Director of Public Instruction, and will be submitted to Government with a report from a Committee consisting of the following gentlemen: The Director of Public Instruction, Mr. C. H. Tawney, Baboo Bhudev Mukerji, C.I.E., and Mr. A. W. Garrett.

With reference to the Indian Famine Report, just issued, it is stated that the questions of tenure irrigation, railways, &c., will be dealt with exhaustively in the second part of the report, which will, it is hoped, be ready for presentation to Parliament, before the close of the session. The first part of the report relates to famine relief; the second deals with the measures by which Government, through its action, may place the people in a better condition to withstand the effect of droughts.

We have before us the last General Administration Report of the Patna division, from which we learn some of the excellent results that have attended an increased cultivation of the sugarcane. Canal irrigation has done much by reclaiming and fertilising waste and barren lands, to develop the area under sugarcane, especially in the Gya district and in the Jehanabad sub-division. In the latter district the canal water, by means of the great facilities it afforded to the cultivators, has given a great impetus to the sugarcane industry. The results of last year's operations, we are told, paid very well, and there is no reason to doubt that the cultivation of sugarcane will continue to extend in the immediate future. Some remarks of the Sub-divisional Officer of Jehanabad are especially noteworthy, and we shall reproduce them here in the shape of a brief extract. He says that :—

"A ryot has made a clear profit of Rs. 80 per beegah by sugarcane. Comparing this with the sum of Rs. 8, which is considered to be a good profit in a beegah of *rubbee* or *khureef*, and that of Rs. 20 which poppy yields, there can be no doubt that sugarcane is the most valuable crop, and that an extensive cultivation of it is more likely than anything else to raise the condition of the ryots. There are no doubt certain drawbacks, namely, that the crops remain longer on the ground than any other, and that the work of preparing the land and irrigating the crops is extremely arduous. Still, the cultivators say that it does not require the same unvarying and engrossing attention that poppy cultivation does. It has been found that the sugarcane has in some places superseded poppy cultivation."

It will be seen that some most important statements are contained in the above paragraph, and we shall be glad to hear of further attention being paid to the subject. Many improvements have been made of late in connection with the sugarcane industry in Bengal. Experiments in agriculture have been carried out by European and native gentlemen, of practical knowledge, and new machinery has been invented and introduced in some parts. Conspicuous among these have been the gentlemen in charge of the Beheea estate—Messrs. Burrows, Mylne, and Thompson—whose new sugar-crushing machine, by reason of the great saving it effects in the outturn, is destined apparently, soon to be universally adopted. According to the Lieutenant-Governor these gentlemen, by their experiments, are "rapidly revolutionizing the whole (cane) sugar industry of Bengal."

Perhaps the most marked instance of success in the way of improvements that do not interfere with the rayat's prejudices is Messrs. Thomson and Mylne's Beheea mill. An improved cane-crushing mill was called for, and these gentlemen responded to the call, with the most gratifying results to all concerned. Their mill has many points to recommend it: first, it is simply the old native mill improved upon, and this is a strong point in its favour. It does not look like an English mill, but has all the characteristics of the old country mill the *kolhu*. Then it takes no more power to drive it, no more bullock power we mean. It would doubtless be easy to construct a mill which should do its work in a very complete manner, if no limit were placed on the power necessary to drive it, but with the average rayat, this is all important. He has a certain amount of bullock power at his disposal, and if you make a demand on him beyond this amount, you at once call on him to make an extra outlay to which he objects. The Beheea mill is worked with the same bullocks which worked the *kolhu*. That is another strong point gained. The patentees claim for it the advantage that half the number of bullocks suffice as are necessary for the other, but to be safe we will say that no more power is required. Then the *kolhu* being a fixture, necessitates all the cane being conveyed to it, whereas the Beheea mill can be moved by four men from field to field, a great saving in cartage being thereby effected. It does not require so many attendants to work it. For the old mill the cane has to be cut into short lengths, and as at the ends of each length fermentation is apt to supervene, it is easily understood that the quality of the juice is prejudicially affected thereby. The Beheea mill takes the cane whole, thus saving the labour of cutting and obviating the chance of fermentation. The juice from the latter sells therefore at 25 per cent. higher price than the other. Besides this, the rollers having more grip, the percentage of juice is larger than from the *kolhu*. Against all these advantages, there is only the drawback of increased cost. The prices are from Rs. 80 to Rs. 95, according to size, a sum considerably higher we presume than the cost of the other, but this does not weigh as a feather in the balance with the rayat, when he sees that this extra cost will be more than recovered in the course of a single season. Consequently we are not surprised to find that over nine thousand of these mills have been purchased in the Shahabad district alone.

We have repeatedly pointed out the absurdity of India purchasing sugar from other countries, when she can grow it so well herself, and we have also made the same remark regarding other articles. A few such successes like that of the Beheea cane crushing mill, and we shall have no cause for complaint left.

A Circular has been addressed by the Director of Agriculture and Commerce in the North-Western Provinces to all persons interested in the improvement of agriculture. The circular makes some very important suggestions, which we make no apology to place before the reader. In the first place the liberal use of bone dust as a manure is recommended. The circular says :— "The great increase in produce which results from the use of crushed bones as manure seems quite unknown to the people of this country, although in England bone dust is extensively

used and paid a high price for (Rs. 3 a maund). On the Cawnpore Farm, during the last *rabi* season, bone dust applied at the rate of 3½ maunds to the acre, gave a wheat crop of nearly 24 maunds of grain and 35 maunds of *bhoosa* to the acre which was 8⅞ maunds of grain and 15 maunds of *bhoosa* more than was gained from unmanured land."

The crops for which bone dust will be found most useful are, maize, sugarcane, wheat, and barley. Then we learn that the urine of cattle is a far more potent manure than their dung. The circular says :—" In Europe it is carefully collected by keeping bedding of grass or straw under the cattle in their sheds, which absorbs all the urine as it falls, and which when rotted is applied to the land as manure. In this country it is inadvisable to use bedding since in the hot weather and rains it harbours insects and rots the feet of the bullocks, but I recommend that an attempt be made to collect cattle urine in the following manner. Have the floor of the bullock shed sloped off to a pit in one corner, and well rammed with clay, so as to let the urine drain off it into the pit. Keep the pit half filled with loose earth, taking out as much of it as is saturated with urine, say, once a week, and replacing it with dry earth. The earth saturated with urine should be kept for 3 or 4 months, and then applied to one-half of a field, and its effect in increasing the produce judged of by comparison with the other half."

Deep cultivation is highly recommended. The chief difference between the Indian and European methods of tilling the soil lies not so much in the *depth* to which the soil is cultivated, but in the fact that the European plough *turns the soil right over* while the Indian plough merely stirs it. Most European ploughs are meant to be drawn by horses, and are too heavy for bullocks, unless two or three pairs are yoked. But a plough on an American model has, we learn, been adopted by this department which is very light, cheap, and simple and which with an ordinary pair of bullocks will plough to a depth of 5 inches and turn the soil completely over to that depth. Many district officers and native gentlemen have used this plough, and given very favourable accounts of it. The Agricultural Department, we learn, is willing to lend ploughs of this kind for trial on application.

The Bengal Government has granted a sum of Rs. 2,000 for the importation of good potato seed from England and Australia, which on arrival is to be planted at Kalimpoong. Some years ago Darjeeling used to be famous for the excellence of its potatoes, and a very considerable trade in this produce with Calcutta and other places existed. Of late years the Darjeeling potato has been steadily deteriorating in quality, and the export trade which formerly existed has in consequence become almost extinct; Calcutta being now almost exclusively supplied with Bombay potatoes. The deterioration of the Darjeeling potatoes is apparently due to the native *jhooming* system of cultivation having become impossible in this district of late years, to the use of inferior seed year after year, and to the native cultivators knowing nothing about the rotation of crops, and never manuring the ground before sowing. The usual practice with the native cultivators is to sell the largest and best potatoes and to reserve only the smallest and worst as seed for the next season's crop, with the inevitable result of yearly deterioration both in quantity and quality. The introduction of a new and improved strain of seed in this district is calculated in time to restore a trade which has, owing to the causes above enumerated, almost ceased to exist, and it may safely be predicted that Government will in a very short time recoup itself for the Rs. 2,000 sunk in the very laudable effort to encourage the cultivation of a better class of potato by the hill people. That really splendid potatoes can be grown in the Darjeeling district is very well known, and the fact has been proved by a local gentleman, who imported some seed from Messrs. Sutton at the beginning of the year, and who planted it out on carefully prepared land. The crop is now being dug, and the results are more satisfactory, the potatoes being fully equal, both in quantity and quality, to English grown potatoes.

The *Pioneer* says that "the Government of India has ordered the extension of poppy cultivation to the Agra, Muttra, Aligarh, and Moradabad districts of the N.-W. Provinces, in addition to an increase in the area in districts where the cultivation at present exists. A considerable increase in the staff of the department, European and native has also been sanctioned. Mr. H. Rivett-Carnac, C.I.E., the Opium Agent, to whom the necessary measures have been entrusted, is now on tour, arranging in communication with local officers, the details of the new scheme."

The Lahore paper publishes a long letter on the Hissar Cattle Farm, and the vast improvements it has undergone under the able management of General Angelo. Beneath his fostering care, the writer tells us, jungles have given place to luxuriant and neatly kept fields, order has ousted disorder, neatness taken the place of untidiness, and economy that of lavish expenditure. He has initiated a new of system of ploughing and cultivation, to see which the zemindars not only flock in crowds to Hissar, but of which they have expressed their approval by adopting it themselves.

The news from the Berars is very bad, we are sorry to say; the clouds are carried over the country by strong westerly winds and no rain falls. A six-anna cotton crop is the utmost that is now hoped for.

A *Daily News* telegram from Alexandria states that the cotton and other crops in Egypt are looking splendid, and that the Nile promises to be equal to last year. Land is increasing in value.

When we are hearing such an outcry from most quarters regarding what is called "the deplorable state" of Indian trade, says the *British Mercantile Gazette*, it is well to look into the facts as represented by recent statistics. As for the financial blunder, that belongs to a totally different aspect of the question, but looking at the returns regarding India's foreign trade, there is no evidence of retrogression, but of steady progress, only temporarily interrupted by the universal depression. During the last ten years the imports of merchandise into India have increased 25 per cent., and transactions in cotton manufactures have gone up 50 per cent. The exports during the same period have increased over 20 per cent. Jute, hides, and skins, opium, grain, seeds, particularly represent a fair increase, but the most remarkable figures are in regard to tea, which has improved 200 per cent. during the last ten years.

The weekly report of the Bombay Chamber of Commerce just issued, gives the details of the trade for the first seven months of the year :—

		1879.	1880.
Cotton	... bales	551,978	816,036
Wool	... "	40,228	59,506
Linseed	... cwt.	421,931	1,400,318
Wheat	... "	8,590	1,075,509
Coffee	... "	90,969	106,895

It will be seen that cotton has increased 48 per cent., wool 47 per cent., linseed 230 per cent., wheat 12,304 per cent. (!) and coffee 18 per cent. No little part of the enormous increase in wheat shipment is owing to the opening of the short distance of the Rajpootana railway. The *Bombay Gazette* says there is still a good deal of wheat and seeds to go forward, and the stock of cotton in Bombay is much larger than for many monsoons, so that prospects for the rest of the year are encouraging.

Ceylon promises to make a good show at the forthcoming Melbourne Exhibition. Tea, coffee, cinchona, cacao, and cinnamon will be among the chief agricultural products, while in the ranks of manufactures the cabinet work of the Kalutara and Galle carpenters will stand well to the fore. Mr. A. M. Ferguson, senior editor of the *Observer*, who goes as the Ceylon Commissioner, carries with him the confidence of all classes, and there is no doubt but that he will do full justice to all Ceylon interests committed to his charge. The Madras specimens have been sent to Melbourne, and, according to the catalogue published, they ought to attract some notice.

Prof. Baeyer has, says the *Athenæum*, discovered and patented a method of obtaing artificial indigo, which is to be worked on a commercial scale by the Baden Aniline Company. The indigo is obtained from chloride isatin which is produced from benzole.

The Rangoon trade in salt shows considerable improvement annually. During the past official year, says the *Gazette*, 1,430,208 maunds of this article were passed through the Custom House for consumption on payment of a duty of

Rs. 1,71,816, while in the year previous, 1878-79, only 905,712 maunds nett, yielding a duty of Rs. 87,697, were consumed. Of the first mentioned quality, 894,323 maunds were consumed locally on payment of a duty of Rs. 1,67,686, at the usual rate of 3 annas per maund, and 535,885 maunds were exported to Upper Burmah and charged with duty at one per cent. of the market value of the commodity under the provisions of the Treaty of 1862. The latter quantity then paid the nominal tax of Rs. 4,130 only, whereas if charged with duty at the usual rate the amount collected thereon would have been Rs. 1,00,479.

NEW rice mills are still the order of the day in Rangoon, amongst both European and native firms. Three new ones are being put up now, and are expected to be ready for working by the next rice season; and we believe one additional rice mill is to be started in both Bassein and Moulmein. Improvements in rice machinery are yearly effected, and with the rapidly extending demand for cleaned Burmah rice in China and South America, there will doubtless be profitable trade for all the new erections in a few years. It is to be regretted, however, that the mercantile community do not interest themselves more in the land question, and move the Government to make more liberal grants of waste land, for the purposes of cultivation. There is no doubt a more liberal system would attract to these waste lands the population and capital which are now confined to the large towns, and if new rice mills continue to be erected in the numbers that they have been of late years, the difficult question for their owners to decide will be where to get sufficient supplies of grain to keep them constantly working. It would, therefore, be advisable for the merchants to look a little ahead, and to do all they can to encourage an increased cultivation of rice, or they may find in a few years that they have gone so far ahead of the present capabilities of the province, that their mills will be forced to remain idle for a great part of the year owing to the inability of the present population to supply them with paddy, or unhusked grain in sufficiently large quantities. The capability of the soil may be boundless, but with the slow rate of increase amongst the agriculturists, which may be put down to the restrictions, red tape, and routine which has to be gone through to acquire land for cultivation, we may shortly find that the milling power in Rangoon is enough to convert the whole produce of the province into rice in a very few months of the year.

OUR Rangoon correspondent writes to us:—Government recently despatched a model of a Burmese kyoung or monastery to the Melbourne Exhibition. Had specimens of our lacquered-ware, silver workmanship, rice and tobacco been sent, I think it would have given the colonists a better idea of the province, and possibly induced some orders from Australia to our merchants and traders. Tea from Arakan and coffee from Tonghoo might also have been exhibited. Both are of the finest quality, and it is greatly to be regretted that unwise land legislation keeps the cultivation of both products backward. Surely to encourage the cultivation of such valuable articles for export, Government might offer land, of which there is such abundance here, free to any company or private person who could shew they possessed adequate means for cultivation, and on such terms that if the land was not used for the purpose it was applied for, or a certain proportion not brought under cultivation within a certain number of years, the land would be liable to be resumed. It can only be by some such liberal terms offered to the first in the field that we can hope to attract capital and population to this province. This has been pointed out over and over again, but still the Government made no move, and only offer leases where they should gladly make a present of the free hold to induce capitalists to come forward.

THE experiments in jute cultivation that have been carried on lately in Brazil are likely, it is said, to turn out a success. Both the soil and climate of the Brazilian lowlands are well fitted for growing jute; in some places two crops a year are obtained. The fibre of the Brazil jute is said to be of a superior quality; and the Brazilians are prepared not only to grow the raw material, but also to start manufactories.

THE *Lucknow Times* gives the following interesting account of the growth and manufacture of Chinese white wax:—

The white wax of Sze-chuen, China, is most peculiar in its growth. We observe that Baron Richthofen estimates the value of the annual crop, on the average at about £650,000. In 1879, upwards of £81,000 worth of this curious entomological secretion was exported from the one port of Hankow alone. White wax is the mere exudation of an insect in a state of disease, aggravated probably by the operation of an uncongenial climate, and favoured by the presence of a tree for which the creature has an affinity. In the Keenchang district, an evergreen, known as the *ligustrum lucidum*, thrives in abundance, and on its twigs in the spring of the year countless flies swarm like a brown film. The branches soon become covered with a white, soapy incrustation that increases in volume until the commencement of the fall of the year, when the sprays are cut off and immersed in water, which is kept boiling. The viscid substance rises to the surface, and is skimmed off, melted, and allowed to cool in deep pans. It was accidentally discovered that by transporting the insects from their native district to the more vigorous one of Keating Fu, in the north of the province, their capability of discharging wax was largely augmented, a property which was promptly and extensively availed of by the Sze-chuen traders. The period between morning and evening is chosen for conveyance, because many hours of sunlight would precipitate the hatching. This should take place only after the females have been attached to the trees. Arrived at their destination, six or more of the mothers—which are enormously prolific—are tied, wrapped in a palm leaf, to a member of the *ligustrum*. A few days later the young flies are swarming on the twigs, where they fulfil their mission by the month of August. Then they perish in the caldrons, where the results of their brief existence are collected. It is said that this peculiar industry requires the exercise of great care, forethought, and experience.

A DUBLIN paper, the *Farmer's Gazette*, says that the durability of wooden posts planted in the ground depends in a great degree on whether they are planted in the position in which they grew or *vice versa*. Owing, it is supposed, to the moisture not being able to ascend against the grain, posts planted top downwards remain sound many years longer than those not so reversed.

SELECTIONS.

THE MUDDAR PLANT.

A MEMORANDUM on materials suited for paper-making that we have received from the Agricultural Department, contains a most interesting monograph on the above weed.

We use the term "weed" advisedly, for though gifted with almost every quality that can make it useful to man, the Muddar still continues a useless jungle plant, that can be viewed in almost every part of India from the windows of a railway carriage—a standing example of how much yet remains to be done before the much-talked of development of the resources that lie at our feet, becomes an accomplished fact. The whole of Rajpootana so far as we have seen it, may be called a Muddar preserve; the plant abounds all over the Punjab and the N.-W. P., is found in moist and marshy Bengal (we have seen a splendid specimen of it in a compound in Calcutta), occurs again in Madras and Mysore, everywhere in fact where there is soil on which to grow, and where no care is required for its growth. In the words of the Report before us, it will grow where nothing else will grow—on beds of sand for instance. But it is equally at home on rich soil; a perfect cosmopolitan in short, that presents itself everywhere whether it is wanted or not, and always with a kind of mute reproach expressive of—"Why do you not make use of me? You could easily do so if you would only take the trouble, in place of frittering away your time on other plants that have not half the good qualities which I possess."

We must confess the Muddar is a perfect pariah amongst plants. Nobody takes care of it, for it takes such good care of itself that it is looked upon rather as a nuisance by those who have an eye for the picturesque. Its tough sea-green leaves are suggestive of leather, and it is only while the pods are bursting and the silky contents floating about upon the wind that the plant can lay any claims to beauty. But that is a matter of opinion. The homely useful qualities of the weed we shall attempt to describe as briefly as possible in the following lines.

So far back as 1852 Dr. Riddell, Officiating Superintending Surgeon of his Highness the Nizam's Army, came to the conclusion that the milky juice of the Muddar, was not unlike guttapercha. After drying, he tried experiments with it in acids, alcohol, liquor potassæ, and spirits of turpentine, and the tests corresponded exactly with the established results of the real guttapercha. Captain Meadows Taylor of the Hyderabad contingent on hearing of these experiments tried another test. A piece of the real guttapercha of commerce and a piece of the new substance, both of the same size, were softened in hot water and united readily. He then submitted the mixed substance to a test by acids, and the results did not differ from those on either of the two original separate substances. In May 1853, Captain Hollings, Deputy Commissioner of

Shahpur in the Punjab, obtained precisely similar results with the juice of the plant grown in that province. He also used the Muddar guttapercha, instead of silk, for isolating wires used for the conveyance of electricity, and he found it to answer very well. He placed a wire covered with the substance in a brass vessel filled with water, and found that the electric spark was carried along the inner wire without interruption. Dr. Riddell sent some specimens of the new guttapercha to be examined by a chemist in London, who put it into the hand of a scientific gentleman, Professor Redwood, who said :—" The substance resembling guttapercha, obtained from the Muddar, I find possesses several properties in common with guttapercha, while in other respects it differs." He tried to vulcanise it (*i.e.*, to combine it with sulphur) but did not succeed, and he did not think it could be deprived of its property of being a conductor of electricity.

No further attempt has been made to solve this problem for more than a quarter of a century !

The next good point about the Muddar is the toughness of the fibre yielded by its stems. Ropes of surprising strength can be made of it, and it is also suitable for weaving as it blends readily with silk. Fishermen in Sind use it for their nets, and the hillmen in the Rajmahal Hills use it for their bowstrings, which are said to last five years in constant use, and exposed to all kinds of weather. Some twine made from this (the Rajmahal variety) bore 248lbs. and 343lbs. in the dry and wetted conditions, when hempen twine of the same thickness bore only158lbs. and 190lbs. in the same conditions. Some experiments on the Madras variety again showed that it bore 532lbs., when the *sunn* of Coimbatore bore 407lbs., the *agave* (aloe) 362lbs., cotton 346lbs., and coir 224lbs. only.

The extraction of the fibre is the difficulty. It has to be picked off the inside of the bark, *not* from the stem itself. Captain Hollings says :—

" The workmen bite through the bark about the centre of its length ; they then hold the tissue of threads in one hand and separate the bars with the other. I have tried hot and cold water, and all the arrangements known for the separation of hemp, or rather the preparation of *sunn* jute, &c., without success ; as yet human teeth and nails are the manipulators, but it is not unreasonable to suppose that some chemical process will be discovered by which the bark will be easily separated from the fibre."

In 1855, practical men in England pronounced the fibre to be well calculated for supplying the place of good flax for making prime yarns, and it was considered at that time to be well worth from £30 to £40 per ton. Here too nothing has been done to improve the methods of extracting the fibre for the last quarter of a century.

The third product of the Muddar is the smooth glossy cotton, yielded by the bursting of the pods, and which resembles short lengths of pale yellowish-white floss silk. In France and Germany this has been worked up into articles of dress, and Messrs. Thresher and Glenny also succeeded in manufacturing a texture composed of equal parts of Muddar floss and cotton, and also a flannel from Muddar in one part and wool two parts. In October 1849, Mr. Monckton, C.S., of Etawah, sent to the Agricultural and Horticultural Society of Bengal some specimens of cloth manufactured from the Muddar cotton. In one of these the warp or longitudinal thread was of common cotton, and the weft or cross ways of pure Muddar. In other specimens the warp was half common cotton and half Muddar, and the weft three parts Muddar to one of common cotton. At the International Exhibition of 1862 the Shahpur Jail gained a medal for its manufacture of Muddar cotton stuffs. And in the Punjab Exhibition some table napkins were exhibited made of Muddar cotton in Dehra Ismail Khan, also towels made of Muddar and ordinary cotton mixed ; also a rug made of Muddar (coloured) from Rawul Pindi.

We have now said enough about the products of this valuable plant. It only remains to add that its cotton is supposed to be peculiarly well adapted for paper-making, and that it is probably in this direction that the Muddar will first be utilised. As his Highness the Maharajah of Gwalior has set an example of enterprise in starting paper mills, he may as well follow up his venture by bringing into use a material which can be had for the picking over a great part of India.—*Delhi Gazette.*

THE RAINFALL OF INDIA.

THE rainfall in India varies greatly. Cherapunji, on the Khasia Hills, north-east of Bengal, has the heaviest known rainfall in the world. Rain is estimated in inches. Every inch multiplied by 14¼, represents the number of millions of gallons which fall per square mile ; each gallon weighing 10lbs. At Cherapunji the rainfall averages 524 inches a year. This means that if all the rain which falls there during a year remained on the ground, it would form a lake 43⅔ feet in depth—sufficient to cover a large house of two stories. On the other hand, in Upper Sindh the average rainfall is only about two inches a year, while sometimes a twelve-month passes without a single shower. Between those two extremes, there is every intermediate gradation.

The rainfall in India is greatly influenced by the monsoons, or periodical winds which blow alternately from the south-west and the north-east. The South-West Monsoon, lasting from May to September, causes two belts of excessive rainfall. One extends from the mouth of the Irrawaddi along the east coast of the Bay of Bengal, up to the valley of the Brahmaputra, and along the skirts of the Himalayas. The other streches along the west coast of the Peninsula, from the seashore to the summits of the ghâts. In both cases, wind from the Indian Ocean, highly charged with vapour, drives against the face of a mountain range. The air in rising expands and is cooled, precipitating therefore a considerable part of its vapour. The rainfall increases with nearness to the hills in the direction of the wind. Thus at Lahore, 100 miles from the nearest hills, the annual rainfall is 15 inches a year ; at Rawul Pindi, near the foot of the hills, 29 inches, and at Hazara, on the hills, 44 inches.

On the *lee* side of a range, that is, on the side opposite that on which the wind blows, the rainfall is comparatively small, the air losing its vapour in crossing the mountains. At Bombay the annual rainfall is 71 inches ; at Mahableshwar, one of the highst points of the Western Ghâts, it is 260 inches, while at Poona it is only 27 inches.

Madras draws its chief supply of rain from the North-East Monsoon. The wind in its comparatively short passage over the Bay of Bengal, does not collect the same amount of moisture as the South-West Monsoon. The avarage rainfall at Madras is about 49 inches a year.

On the west coast most rain falls from May to August ; in the Carnatic October and November are the wettest months.

In the north-west corner of India there is an arid region, including all Sindh and half the Punjab, where the average annual rainfall is less than ten inches. Next, there are two zones of dry country, with an annual rainfall between 15 and 30 inches. One, named the Northern Dry Zone, surrounds the arid region on the north and east, in a belt from 100 to 200 miles wide. It includes Delhi and Agra. The Southern Dry Zone is in the peninsula, extending from Nasik to Cape Comorin at a distance between the two seas. The next region has a rainfall between 30 and 60 inches, and includes the upper part of the valley of the Ganges, Central India, and the eastern coast of the Madras Presidency. The deltas of the Mahanadi and Ganges, and the lower part of the Ganges Valley have a rainfall between 60 and 75 inches a year. The coast of Burmah and part of the west coast of India have a rainfall of above a hundred inches a year.

The rainfall of a few other places may be mentioned.

The highest known rainfall at Calcutta for 35 years was 93 inches ; the lowest but one, 41 inches. The average is 66 inches. According to Parkes, Benares has, on an average, 37·4 inches annually ; Agra, 28 inches ; Delhi, 25 ; Meerut, 1[illegible] ; Nussorabad, 15·8 ; Peshawur, 13·7.

At Madras* the highest known rainfall for 67 years was 88·41 inches ; the least was 1[illegible]·45 ; the average 48·56. The rainfall at Moulmein is said to be about 180 inches a year.

Colombo, Galle, and Kandy, in Ceylon, have nearly the same annual rainfall,—about 80 inches a year. The rainfall in the north of the Island is only about half that on the south-west coast. At Ambagamuwa, the average is about 20[illegible] inches a year.

THE GROWTH OF BARLEY.

I WAS much struck with two letters which appeared in your valuable journal some weeks ago, the first from INQUIRER, asking for information from some of your numerous readers, respecting the barley crop of 1879 ; the other letter, signed BOTHERLY HELP, quoting an extract from a speech of Mr. Gladstone's, in which he rebuked farmers for the want of mutual interchange and communication of successes and failures in their business. As a proof how well we farmers deserved the rebuke, we find but two of our *profession* troubling themselves to give the asked for information. If the details of the different experiments made by many of us were given in our agricultural papers (of which we consider yours one of the best) much time and expense would be saved to many beginners, as they then would have simply to refer to their extracts from your Journal, and find whether or not their idea was worth trying. With your permission I will set an example by giving you a few of the wrinkles I have learned during the last thirty years in preparing the land for growing the best quality of malting barley, which is, from all accounts, to be one of the principal mainstays of the British farmer for years to come, the area where it can be grown being so small, and the demand likely to be large as soon as trade revives and our mechanics have plenty of spending money.

On no single subject connected with farming have I found such a diversity of opinion as on the preparation of land for the barley crop. If we take the Norfolk farmers for example, you will find one who will follow with his plough immediately after the sheep fold, just turning over the land with a furrow two inches deep, his neighbour will break his land up six or eight inches deep, with a plough without a breast. This will leave the droppings of the sheep as near the surface as his neighbour has done, and besides, will, by breaking up the land, have rendered it less likely to suffer from heavy rain or drought. They both will follow with

* The following statistics may interest some of our readers. Average monthly rainfall at Madras ; January, 0·95 ; February, 0·28 ; March, 0·44 ; April, 0·68 ; May, 2·87 ; June, 1·99 ; July, 3·79 ; August, 4·53 ; September, 4·74 ; October, 10·84 ; November, 18·97 ; December, 4·98. *From Madras Observatory.*

The *Madras Adminstration Report*, for 1877-78, gives the average rainfall of the districts for ten years previous to 1876-77 :—Bellary, 22·34 inches ; Coimbatore, 23·71 ; Tinnevelly, 26·91 ; Kurnool, 27·38 ; Cuddapah, 28·01 ; Madura, 28·81 ; Kistna, 30·41 ; Nellore, 33·47 ; North Arcot, 33·88 ; Salem, 34·66 ; Godavari, 36·49 ; Trichinopoly, 37·06 ; Tanjore, 37·87 ; South Arcot, 38·29 ; Ganjam, 40·48 ; Vizagapatam, 41·01 ; Nilgiri, 44·68 ; Chingleput, 50·64 ; Madras, 53·33 ; Malabar, 107·95 ; South Canara 136·60.

another ploughing just previous to drilling the barley. The second is the system from which I have seen the best results. Again, you hear another light land farmer as strongly recommend ploughing but once after the sheep fold. This may answer in a favourable season, when your land suffers from neither heavy rains nor droughts, but it is not one that I would recommend. Then, with respect to the mixed soils and so-called heavy lands of Norfolk, you find just the same variety of opinion. My experience, and what I could learn from successful barley growers, convinced me that it was necessary to get the major part of the land folded and ploughed up before Christmas, giving it one fair earth of some five or six inches deep, then letting it lie until the latter part of March. Then scarify it across the furrows, harrow, and drill from six to eight pecks of the best barley you could obtain, and hope for the success you deserve. By the coast you find still another plan in operation. They grow heavy crops of swedes and white turnips, all of which are carted either on to the wheat stubbles, and there thrown about for the bullock to blow themselves out with, or are carted home and given without stint to the bullocks in the boxes. The land is then ploughed once, and sometimes twice, about three inches deep. Then in April they drill from three to four bushels of barley per acre, and, as any one out of the district would suppose, they grow a heavy crop of weak soft straw, with an equally light crop of inferior barley. One or two outsiders adopted the plan of feeding a third of the roots on the land, then first ploughing it six inches deep without the breast, and afterwards about four inches in the usual way; drilling in March from eight to ten pecks per acre, with a marked improvement both in quantity and quality.

The system of growing barley after wheat has very much increased of late years, neither the crops of straw nor corn are so heavy as after roots, but the quality of the barley is generally much superior and more suited for malting purposes. The cultivation found to answer best is ploughing the wheat stubble in, soon after harvest, then another earth in January or February, the manure being applied during the frosty weather. If any artificial manure is used, it might consist of two to three cwt. of superphosphate and one cwt. of nitrate of soda.

The growth of barley on heavy clay lands has also come more into favour since the price has increased, and that of wheat decreased. The usual cultivation is as above, if it is grown after wheat; and if after dead fallow, the land is summer-fallowed in the usuel way, mucked in autumn or winter, and again ploughed during the winter. The first time for this last operation is when there is a frost, which will require to be very severe to prevent one's getting on with this work; the land will then fall down like lime, and take but little working when the barley is drilled. Two cwt. of superphosphate will improve the quality of the crop.—*Cor., L. S. Journal.*

ABOUT PAPER FIBRES.

WERE we to ask any ordinary reader what paper is made of, the answer would probably be promptly "rags, of course." This is so nearly correct that if it be recollected as the leading idea in the subsequent remarks on materials for paper-making, they may prove interesting, if not, also useful. The Government have for some time been inquiring as to India's capabilities for producing such materials, and the results of those inquiries in all parts of the country have been curious and will probably be utilised by commercial people.

We associate the word "rags" chiefly with cotton and linen rags rather than with woollen. Woollen is unfitted for paper-making, but the other two materials well represent almost all others. The one, cotton, is a fibre derived from the "seed-vessels" of a plant: the other is fibre from the "stock" of a plant. Cotton is the commonest material, and India is the home of cotton. Then, say some, the question is settled, 'let India sell cotton to the paper-maker.' But this will by no means do. The paper-makers cannot afford new cotton; old rags easily collected are good enough for them, and the price is incalculably cheaper. It will not do even to send refuse waste home. The question is, is there no other cheaper source of fibre in the jungles or deserts of India, which will pay to collect and export.

Our first inquiry is, what are the exact requirements as regards such a fibre. This is answered by the curator of the Victoria and Albert Museum, Bombay. "To be successful, a raw material for paper-making should possess certain qualities. The first and most important is an abundant and lasting supply easily procured, and cheaply prepared for exportation; nor should its bulk be too great. When in the hands of the paper-maker, it should work up cleanly, and at a moderate cost, and present no difficulties in bleaching: a fibre should have a certain amount of roughness to enable it to 'felt' or cohere in the massy, and lastly it ought to turn out at least 50 per cent. of good marketable paper."

First, as regards "an abundant and lasting supply," it is unlikely that it will ever pay to cultivate good land for this special produce, unless systematic paper manufactories were started in India itself. To this point we shall afterwards revert. But it appears from the various reports returned to Government that some of the best fibres are produced on land otherwise useless. Some grow in thick trackless jungles: some, such as the bamboo, in endless forests in difficult tracts; others, such as the *muddar* and certain grasses, in ground otherwise perfectly sterile and desert; and others in equally useless swamps and marshes.

This then, to start with, is very hopeful. It is said that the wise, good hearted Linnæus defined a *weed* as "a plant whose virtues and uses have not yet been discovered." If the weeds of our immense deserts are discovered to be useful articles of commerce as regards the important art of paper-making, weeds merely waiting to be gathered and sold, no doubt an impulse will be given to investigation in many other similar directions. The question of bulk in packing is of course an important one as regards cost of transport and freight, but, if the fibre is worth having, doubtless processes would soon be invented to eliminate the rubbish from the useful part and economise the bulk of the latter, just as in the wool-trade it is the most economical plan to clean it before despatching it to consignees, who do not wish, if they can help it, to pay freight for filth, mud, and refuse. The bleaching is more a question for the manufacturer than for the collector of the fibre, because if it is good for bleaching at all, the maker perfers to do it himself, from the beginning of the process. This therefore need not trouble the exporter: what he has to see to is that the fibre is what the maker will buy.

The question of "felting" of the fibre is a curious one to those who have never seen a paper mill. It is not a question of long or short fibre, or of fineness or coarseness. It is not whether it will make fine tough threads or close lasting fabrics. It is simply this: given a fibre which must be cut, torn, and minced and pounded into particles so minute that they cannot be distinguished except by a microscope; so minute that when boiled and mixed with water, they merely make it like milk or cream, so like butter-milk, indeed, that you could not tell the one from the other; yet, if that creamy fluid is poured out anywhere on a fine sieve or a flannel cloth, or some such surface, and pressed and dried, it will form a firm felted mass such as we can best describe by telling the reader to examine coarse blotting paper. One would think that any stuff that would thus make a pulp would make paper. For example, some juices make a pulp and turn out India-rubber and guttapercha. But paper pulp is quite different and its requirements special.

We come now to the consideration of certain substances that fulfil or partly fulfil these requirements. A number of them we are wholly unacquainted with, but there are some with which every one is more or less familiar. We have already set cotton aside as too valuable to be cultivated solely for paper. But flax deserves attention. In many parts of India the stem is wholly thrown aside as refuse, the seed alone being valued for making oil. A great industry seems possible in flax fibre, which at present is only used for string and rope. So also is *sunn* or tow, from which a good deal of native paper is made, but even that is often mixed for paper with a certain amount of cotton. The American aloe is counted a specially valuable fibre. When pains have been taken with it, it turns out first-rate, and is remarkable for the extraordinary strain it stands when made into rope. But at present no economical process has yet been invented to eliminate the fibre from the refuse easily and cheaply. When this is done, it will attract more attention. The leaves of the wild date palm appear to be a very promising fibre. The palm grows in the most miserable sandy deserts and down the Indus Valley in great forests, only utilized by the natives for toddy making. As toddy-drawing spoils the fruit, but does not kill the leaves, there seems a hope that the licenses for toddy drawers may, some time or other, be printed on paper made from the leaves of the trees themselves.

Sugarcane refuse, which is now made into ropes for wells, &c., is also a substance that is now wasted in great profusion. In the United States, the home of economy and invention, the refuse is greatly made use of for the coarser kind of paper, and doubtless if we had local paper mills, we should also use up much of this for the same purpose.

From the above enumeration we have omitted all we did not think of much importance, and those also we thought of extra importance. One of the latter is the plantain. It cannot affect the Punjab much, so we may let it pass. The next is the bamboo. The bamboo grows freely in great forests all along the base of the hills. It already furnishes an important traffic, and it appears that its fibre is very valuable for paper. The Chinese have used it from time immemorial. It would scarcely pay to send home, but it grows just in the places where Indian paper mills would necessarily be started, that is about the clear streams of the lower hills, so that it is especially important to consider it always as a source of supply upon which a paper company could depend.

In the Government Report it seems to us that the river-side grasses have not received enough of attention. Perhaps it is our misfortune that we do not recognise the various *hibisci* under their scientific names, but if they were thought valuable, they would probably be better described. Yet the two most ancient papers in the world were swamp reeds—papyrus and rice. Moonj grass is barely mentioned, yet its fibre is incontestably very valuable. Rice straw is noted merely to be passed over. Wheat straw, which is here pounded up into bhoosa, if capable of making good useful paper. Wild bhung gives a very strong fibre and grows wild everywhere, especially in the hills; so common is it that its young leaves alone sell for about a rupee a maund as an intoxicating medium.

And lastly, we recur to a plant which we mentioned incidentally towards the beginning of our remarks It is called in Punjabi *muddar*. Every one knows it. You have only to glance over the Anarkulli maidan to see it growing everywhere—a shrub about three or four feet high with thick greenish blue leaves and a thickish stem, generally considered an instrusive weed. As for the jungles, it grows everywhere over them and on the bare plains of Mecan Meer just as it does at the back of your cook-

house, it is not particular. If you give it a flick with a whip, instantly milk springs out from the leaf. If that milk gets into your eye, it will blind you; if it is rubbed on your skin, it will raise a blister; if cows or sheep eat the plant, they will die; if goats eat it, it improves their digestion. If you collect the milk, it will form guttapercha, and can be worked in the same way and submitted to the same tests. It has, at the proper seasons, a large violet coloured flower which turns into a seed pod, which when it opens, displays a beautiful floss-silk down which the wind scatters everywhere. This down makes up into a beautiful fabric, but it has not been much experimented on. It makes, we may remark confidentially, a most beautiful stuffing for pillows, rezais, and cushions. But its chief importance is that it has been found to be a splendid fibre plant. It bleaches beautifully, it is very strong, and it turns out an economical paper even when gathered in the jungles here and sent to England. In short, to recapitulate, it produces "a first class fibre, tenacious, elastic, and lustrous; and a cotton silk-like, smooth and glossy; and a juice with some of the properties of gutta percha," and certain medicinal qualities which have only partially been investigated, and it grows profusely as a weed in the worst and most desolate soils and regions of the Punjab. Its scientific name is *calutropis gigantia*, or C. Hamiltonii.

The above remarks have all had reference to the export of fibre for the English mills. But why is so little done in India? Whatever is done must be done in the pleasant little lower hill valleys, the land of clear streams and bright foliage. But, as yet, no railways approach these districts, and until feeders are thrown out to the foot of the hills, we shall see no such enterprise flourish. Beer seems to flourish apparently, because people will drink beer when they hate the very sight or mention of paper. Sugar in the Punjab has as yet scarcely had a fair start, combined with rum, will probably make its own way. Whisky distilleries have not started yet, all the Scotchmen hereabouts being busy as yet in less congenial but more urgent labors. Wool mills are in a similar state of dubious popularity. But we prophesy that the next company will be a paper mill, and would indicate the localities of Kalka, Hooshiarpore or Pathankote as very suitable places for such a venture.—*Civil & Military Gazette.*

SUGAR-CANE IN AUSTRALIA.

THE different varieties of sugar-cane removed from the Botanical Gardens in 1878, to a portion set apart for them in the Oxley Reserve, have thriven exceedingly well, and answer in every respect my most sanguine expectations. The whole appear to be in a thoroughly healthy state, many of the canes having joints from 8 inches to 9 inches in length. I had intended this season to have each variety tested as to sugar-producing capabilities, but, considering the comparatively recent removal, and finding some difficulty in forwarding the cane to the mill, I have decided to allow the test to stand over until next season. Specimens of the principal varieties will be exhibited in stools at the forthcoming exhibitions. During the past year I have received the following:—From Hawaii—*Saccharum officinarum*, var. *Mamulele*, Striped Bourbon or Black Striped; from Singapore, Saigon, and China—*Blanche du Cap*, Gingan, Chinese, Annamite Vamboir, Coki, and Diard; making in all a most valuable addition of 78 new and different varieties, all of which are now under successful cultivation. Promise has also been received from H. Murton, Esq., Director of the Botanic Gardens, Singapore, of varieties of cane from Pondicherry, which will be most acceptable as an addition to those already in our possession. This gentleman has always evinced a most lively interest in the progress of the sugar industry in this colony, and it is to him specially, and others in the southern islands of the Pacific, I am indebted for the most valuable specimens of cane we possess. From the period of my first entering into the duties of these gardens in 1864, I have endeavoured to collect as many varieties of sugar-cane as possible, not only up to the time of its cultivation in the colony as a commercial industry, but up to the present, and by closely observing them during their growth, and noting their peculiarities as to climatic and other natural requirements, have invested the collection with an amount of interest which will, I am persuaded, prove to be of considerable value in the future. Both individual experience and correspondence prove that the use of one class of cane, continued for successive seasons and extending over many years, materially deteriorates the quality; and the substitution of new varieties, to ensure successful growth and productive qualities, becomes imperative.

The applications for cuttings have not only become very numerous, far exceeding those of previous years, but have arrived from various parts of the world where the growth of sugar is an established industry. Different varieties suitable to the climate have been forwarded by request to the West Indies, South Carolina, and other States of America, the Sandwich Islands, Hawaii, and the Mauritius (no less than two tons weight of cuttings having been sent to the latter place), all of which were supplied from the plantation at Oxley previously referred to. I am glad to be able to report, also, that the demands for cuttings from the various districts of Queensland, from their large extent, show in a marked degree the increasing popularity this important interest is gaining with our agriculturists. Rockhampton, has not hitherto been tried as a sugar-producing district, in a commercial point of view, although I have repeatedly called attention to it, as possessing a climate suitable for its cultivation. I am, however, glad to say that an experimental plantation is about being formed by a Mr. Hall, of Rockhampton, consisting of about fifty acres of selected ground, and I have arranged to supply him with sufficient cuttings (98,600) of suitable varieties to plant twenty acres of ground, in the hope that with proper skilful attention the venture may prove a success, and become the pioneer of more extensive operations conductive to the permanent establishment of the industry in the district. Instancing the large proportions to which sugar cultivation has attained in this colony in a comparatively few years, I find the following results, obtained from official sources, of the operations for the year ending December 31st, 1878:—

Areas under sugar-cane	...	...	...	16,584	acres.
Acres of sugar-cane crushed	...	...	...	11,005	„
Sugar produced ...	...	...	...	12,356	tons.
Raw sugar exported ...	...	...	...	3,380$\frac{13}{20}$	„
Refined sugar exported	...	...	...	754	„

whilst the importations for the same period amounted to 250 tons of raw, and 51 tons of refined sugar. The quantity of molasses manufactured considerably exceeded half a million gallons, and the quantity of rum distilled, over 200,000 gallons—a vast and notable increase during the space of eleven years; the number of tons of sugar manufactured in 1858 being reported as 619. I am also credibly informed that the acreage under cultivation at the present season is considerably beyond that of last year, and the crushing has commenced under most favourable circumstances with every prospect of a most satisfactory yield.

The disease, or rust, which has made its appearance upon some of the plantations in this colony still occupies the attention of the growers and scientists, but, notwithstanding continual experiments both here and upon specimens specially sent to England for the microscopic examination of most eminent men, nothing definite or conclusive has yet been arrived at as to the actual cause of the disease, although the effect of it, so far as the rust is concerned, is generally conceded. Professor Liversedge, of the Sydney University, attributes the disease *to defective conditions of cultivation*, and I am still of my previously expressed opinion, which is corroborated by the majority of the planters with whom I have been in communication on the subject, that the true cause of the disease is the climatic changes to which some of the canes have been subjected, by being removed from their natural habitat, and being of too weak constitution to sustain the extraordinary claims upon their being placed under an uncongenial influence; and experience has shown that where diseased cane has been removed to a position where the temperature assimilate with its original growth, the disease entirely disappears. I may also, with equal confidence, express my opinion that the disease is not contagious, for I have witnessed in plantations, where several varieties have been planted in close proximity to each other, some were to be found afflicted strongly with the disease, whilst others of a more robust nature in their immediate vicinity were entirely free from it. Another and most important question arising out of this vexed question is, how far the disease retards the growth of the cane or reduces the density of the juice? This is a matter not yet touched upon by those who have made this inquiry a speciality, but, so far as I can understand from those most interested, the damage is slight, if perceptible at all.—WALTER HILL, Brisbane, in *Journal of Applied Science.*

SERVICES OF BIRDS IN AGRICULTURE.

PEOPLE often venture the statement that every object in Nature is of some use, directly or indirectly; but I fear if they were questioned as to the precise use and benefit we derive from certain members of the animal and vegetable kingdoms, they would find it rather difficult to prove the correctness of their assertion. Among the many natural enemies of the cultivator of the soil, slugs, snails, grubs under, and weeds on the surface, form a large and by no means contemptible part. That it were useless and unavailing for man himself to endeavour to exterminate these pests, is undeniable; and the only help he can expect must be from birds who, in their search after food, are unwittingly of immense use to him, some of them carrying destruction amongst the animal pests, and others against the vegetable ones. Some notes and facts on these services may not be out of place in this journal, and we will first take an insight into the way in which the former are kept under; of course the eventual extinction of these pests is not to be hoped for.

Amongst all our larger birds the *Corvidæ* or ravens are far and away the most aiding to the farmer, and of these the Starling shows to the fore in a useful aspect, its services being something, incredible; slugs, snails, worms, and beetles all form indiscriminate food for this most valuable bird. Statistics in such a case may seem odious, but I believe a German naturalist, with the extreme perseverance characteristic of his nation, once computed, and not incorrectly, that a single young Starling will stow away 140 snails in 11 hours out of the 24. Now, if we deduce further facts from this, we soon see what a valuable aid to the cultivator the Starling is and how deserving of our protection. Nor is there, as far as I know, any set off against these good works; the Starling never attacks plants or grain of any kind, but will search with great diligence amongst new-sown wheat after noxious things, especially young slugs and worms.

Passing to our old and well-known friend the crow, we find that we are indebted to it also for services which, although rendered on behalf of itself, benefit us in no small degree. Not only grubs and their countless more or less distant relations fall victims to their accommodating and lasting hunger, but insects of all sorts and sizes, whose unwelcome pre-

sence is so detrimental to the soil on or in which they are, besides mice, which they destroy in great numbers and greedily devour.

The old discussion, whether the rook does more mischief than good, or *vice versa*, crops up continually from time to time, and the same old arguments are put forward by both sides to prove what is really a question more of locality and circumstance than a general one. Under certain conditions I consider the rook to be a nuisance, and under others a thing to be sought after, and therefore, without offering an opinion, I will state the facts of the case, and leave others to draw their conclusions. For the most part the food of the rook consists of cockchafers and their exceedingly destructive larvæ, besides slugs, worms, and grubs in lesser quantities: but it is also exceedingly partial to fruit, corn, and seeds of all kinds, not to mention young ducklings, chickens, young hares, rabbits, and game of all sorts. Then it must be allowed that the number of the former that they destroy is very considerable, especially the cockchafer larvæ, the liking for which they alone seem to have amongst birds.

Another exceedingly useful member of the *Corvidæ* is the jackdaw, but it is not nearly so plentiful as the crow and rook; consequently—for the same reason that white sheep eat more than black—they do not destroy so many hurtful insects as their [illegible] relatives. Insects, snails, worms—in short the whole category of the animals, are devoured by the jackdaw, especially grubs in ploughed land. Mice [illegible] form a part of their food, and they eat a little corn as well, but not much; in fact, the loss could never be noticed.

One cannot help admiring the wonderful and surprising instinct of these three birds in discovering the whereabouts of the animals and insects on which they feed. They seem to be guided to the exact spot, and all they have to do is to thrust in their beak and draw out whatever may be the unlucky victim. It is curious that the ravens should include amongst their members really useful birds, thoroughly worth the farmer's protection, and birds so undeniably destructive as the magpie and jay, the [illegible] even more so than the latter. The mischievous and hurtful propensities of the magpie are only surpassed by its extreme daring while in search of its food. The first of these two birds eat a minimum of insects, and feed chiefly on fruit seeds, corn, in fact anything it can find to suit its by no means dainty palate; and does incredible harm in field and farm-yard. What is more the crow gets blamed for a great deal of the mischief the magpie perpetrates, I doubt if there is any, among all the birds we are proud to call British, whose mischievous propensities are so widespread.

Although the jay is not quite so unwelcome on farmer land as the magpie, still it is a bird whose room is always preferable to its company, for it is most impartial as to what it eats. Like the magpie, it will consume a few insects, but while it can get corn or seeds in plenty, coupled with an occasional duckling, or chicken, it will always prefer this comparatively easily collected food to the mere scarce and less tasty and satisfying insects.—*Moorman, in L. S. Journal.*

THE CAWNPORE EXPERIMENTAL FARM.

THE experiments made in the Cawnpore Farm last year, as detailed in the report for the *rabi* season, 1879-80, seem to have been of a more practical kind than usual, and remind one of the doings at Sydapet in the Madras Presidency. The first series referred to in the report under notice are those made with different kinds of manuring. We are sorry to see that no attempt was made to introduce poudrette, which has, of late become so popular among the cultivators around Poona. The manures tried were—bone superphosphates, dissolved guano, and green manure consisting of a crop of indigo ploughed in. The table recording the result is so interesting that we make no excuse for transcribing a part of it:—

Manure applied per acre.	Outturn, grain.	Straw.	Total value.			Cost per acre.			Profit per acre.		
Mds.	lb.	lb.	Rs.	A.	P.	Rs.	A.	P.	Rs.	A.	P.
Bone Superphosphate, 2 mds.	1,627	2464	49	10	8	27	12	9	21	13	6
Ditto, 8½ mds. ...	1,894	2,937	59	0	11	31	4	5	26	12	0

No manure	1,171	1,662	35	4	7	19	12	3	15	8	4

It will be observed here that guano stands low in the matter of profit. This was brought about by the great cost of laying the guano down at Cawnpore, amounting to Rs. 9-14-8 per maund equal to Rs. 270 per ton, a price which practically placed it out of the competition. The bone superphosphate, obtained by crushing bones, and treating them with sulphuric acid and hot water, furnished a manure, which cost Rs. 3-7-3 per maund, and could, in fact, be made much cheaper were it not for the very high cost of, and frieght on, sulphuric acid. This solvent stands the cultivator in 8 annas per lbs. at Cawnpore. Three-and-a-half maunds per acre raised the produce from 19·5 bushels—the outturn of the standard and unmanured plot—to 27·1 bushels per acre. It must be remembered that the whole of this soil, having been more or less under experimental treatment during the past three or four years, was in better condition than the ordinary soil of the country, hence the high outturn of 19½ bushels per acre. We should mention that wheat was the crop experimented with. Mr. F. N. Wright speaks of this rather as "a full average outturn for good lands, under the native system of cultivation." We must point out here that the general average all over India is 14 bushels, therefore 19½ is a high outturn, and 27 a striking illustration of what high cultivation can do. The cost of each experiment is very carefully debited—a matter not always attended to in these experiments. For instance, the land being on a Government farm, it is customary to ignore rent. This is unfair, and in this series of experiments, the cost has been made up as follows:—

	Rs.	A.	P.
Rent	6	4	0
Irrigation	3	12	0
Cultivation	8	8	8
Total, Rs.	18	8	8

The rent is based on the average rent of 12 fields adjoining the farm, and the outturn is valued at the rates current at Cawnpore when the grain was ready for the market. The experiments, therefore, have a value not always to be found in such trials, and they are conclusive as to the benefits of manuring. When will the ryot understand that he has just the same rent revenue, and canal dues to pay whether his crop is 14 or 27 bushels per acre; or, in other words, whether his profit is Rs. 10 or Rs. 26, per acre per crop? It is worthy of note, too, that the amount of straw—the value of which was included in the above tabulated figures—was very much increased in amount, and when farmers use this for cattle-feeding, it must be of great value to them. The increase on the plot, with 3½ maunds bone manure, was 75½ per cent. Not the least interesting feature in this series of experiments is the result obtained from the so-called unmanured plot. It is true that no manure was applied with the crop, but in 1877-78, a mixture of blood and bones, to the extent of 5 maunds per acre, was applied, and it is well known that the effects of bone manure are lasting, as was clearly shown in this plot producing 19½ bushels per acre, which is 39 per cent. above the average of India. A second series of experiments was tried, in order to find the effect of carefully selecting seeds, instead of taking it at random from the *bunnia*. The result was a wheat crop of 23¾ bushels per acre from the selected seed plot against 18½ from the other. The respective merits of thin and thick sowing were tested, and resulted in favor of close sowing.

We do not, however, consider the experiment to have been at all a fair one, as the amount of seed, used for thin sowing, was ridiculously small, being only 16lbs. per acre, as against 116lbs. This, we consider, to have been too extreme a test. Two plots were alike treated to 50 maunds farmyard manure, and in every other respect, except irrigation, they were treated in the same manner. The unwatered plot yielded 17 bushels grain, and 24 maunds straw, while the irrigated plot gave a return of 30½ bushels grain and 41 maunds straw, the extra cost of watering having only amounted to Rs. 3-12. Some experiments were made in the way of introducing wheat and barley from England, America, and Australia; and the general conclusion arrived at seemed to be in favor of improving the indigenous variety by careful selection. This, we believe, to be a thoroughly sound decision. Dr. Forbes Watson has told us that, in many districts in India the finest wheat in the world is grown; and there does not seem any reason why we should not indent on those districts for seed wheat to replace the more common varieties of other places. The Indian ryot has been for centuries engaged in cultivating the same grain on the same fields, and deterioration has invariably been the result of such a course all the word over.—*I. D. News.*

CITY REFUSE AS MANURE.

THE importance of having an adequate supply of manures in this country cannot be exaggerated. Mr. James Caird, the great authority in such matters, has, by carefully conducted experiments, proved to demonstration that the difference between the best and inferior agriculture on the same *soil* may be more than treble the produce. Wheat grown without manure yielded 730lbs., and wheat grown with special manure yielded 2,342lbs. The great difficulty in the way of the introduction of improved methods of tillage in India is the want of a sufficient supply of manures. The Indian cultivator must afford to manure his fields properly, and that is the main reason why the soil is becoming gradually exhausted. Such being the case, a peculiar interest attaches to the experiments now being made at Poona to utilise city refuse as manure. The use of poudrette as manure was unknown in the Bombay Presidency until recently; but the Poona Municipality has now been realising a considerable revenue from the sale of poudrette since the opening of the Mutha Canals. Some information about the manufacture and sale of poudrette in Poona will no doubt interest the reader. The population of the city is 90,436 souls. About forty-four cartloads of night-soil, equal to 575 cubic feet, are collected daily, and carted out to a depôt at the village of Dhanpodi, two and-a-half miles off from the extreme limits of the city. Then there are the street and house sweepings collected from the dust bins of the city. They amount to sixty-five to seventy-five cartloads, equal to 1,950 cubic feet, per day. These are carted out; and when burnt and sifted, the produce is 300 cubic feet of ashes. The process adopted in the preparation of the night-soil of

the city of Poona into poudrette is what is called the sun-drying process. The 575 cubic feet of night-soil shrinks in drying to 430 cubic feet of night-soil. Mixed with 300 cubic feet of ashes the produce is 730 cubic feet poudrette per day, or 226,450 cubic feet per annum. Experience has shown that to ensure thorough deodorisation, complete freedom from stink, and the best poudrette, the proportion of ashes to night-soil should be about equal; but as this is not now the case, the supply of night-soil being 430 cubic feet, and that of ashes 300 cubic feet per day —the Municipality are now trying to augment their collection of ashes to the required amount. The price realised is one rupee per cubic yard, or 27 cubic feet. The annual value of the poudrette prepared and sold by the Poona Municipality is Rs. 9,870. The revenue realised by the Municipality from this source has been steadily increased. It has risen in five years from Rs. 766 to nearly Rs. 10,000. The cost of conveying night-soil and sweepings to the depôt comes up to Rs. 11,736; but as this cost has to be incurred in any case, it need not be taken into account. The manufacture of the poudrette costs Rs. 6,264. The annual revenue from the 266,450 cubic feet of poudrette prepared by the Poona Municipality is almost Rs. 5,000. The Secretary to the Municipality thinks that this revenue is susceptible of considerable development. The expenditure for removing the refuse of the city and the cost of preparing it into poudrette can be reduced by Rs. 3,000, while the sale proceeds of the manufactured article can be raised to Rs. 7,500 by increasing the price of the manure. The Secretary to the Poona Municipal Committee makes the following remarks on the value of the manure prepared by the Municipality :—"The manure prepared in this manner is much valued by cultivators, and is in great demand. Applications for the manure have been increasing since the opening of the Mutha Canals, and consequent extension of wet cultivation. Five years ago agriculturists would not touch the poudrette then prepared, and could not be induced to take away at even a nominal charge. At the present moment the outturn of manure is not enough to keep pace with the demand, and it has become necessary to take special precautions that the poudrette is not taken away in its raw state which the cultivators sometimes attempt to do. They frequently pay for manure from four to six months *in advance*, in order to ensure a timely supply. The poudrette manufactured by the Municipality is clean and free from brickbats, broken glass, and other rubbish or common earth. This is secured by the ashes being sifted before being mixed with the night-soil." Those who are never tired of speaking of the prejudices of native cultivators as an insuperable obstacle in the way of agricultural reform in India, should carefully note the facts recorded by Mr. Narso Ramchunder, Secretary to the Municipal Committee of Poona. That the cultivators did not touch the poudrette, when it was first prepared five years ago, was no more than what could have been expected. But as soon as they found that the use of the manure would prove remunerative, their prejudices at once vanished into thin air. They are now so anxious to have a supply of the manure that at the present moment the outturn of the article is not enough to keep pace with the demand, and that cultivators frequently pay for manure to the Municipality in advance, in order to ensure a timely supply. A fact like this is enough to overcome a thousand speculations. Show the Indian cultivator that he will be a gainer by the introduction of any new method, and he will be at once found ready to adopt it. It may be supposed that the manufacture of the refuse of the city of Poona into poudrette is carried on in such a way as may prove injurious to the public health. But we are glad to see that there is no ground for such a supposition. The Sanitary Commissioner of the Presidency has placed on record his opinion that the management of the depôt reflects the highest credit on all concerned. "I have," he says, "visited it often and unexpectedly, and remembering how rude are the means as they generally are in India, I can answer for it that every process is very carefully conducted." The example set by the Poona Municipality should induce other Municipalities in India to utilize the sewage of their town.
—*Deccan Herald.*

CACAO PLANTING.

THE cultivation of cacao in this island has for some time past assumed proportions which promise to render it, at no distant date, a very important feature of our local industries and the increasing favor in which the article is held at home, added to the decline in its cultivation in other countries, seems to indicate a steady demand for it at remunerative prices.

There is no published account of the mode of cultivating the tree, and preparing the product, and the letters from the father of Ceylon planters on this subject, did not convey much that was new or of a practical character. There are accounts of the article by Simonds and other writers, but these are of a very general nature and chiefly statistical, and of little practical value therefore to the planter. We think it may be useful to many of our readers if we place before them our own experience, and such information as we have gathered on the subject.

To begin at the beginning, we may say to the cacao planter, choose well-sheltered land with a deep soil as cacoa is deep rooter: the more loamy the soil is the better, rocky or stony land should be avoided. As to shade we believe that it *is* necessary, and we cannot think of a better shade tree than the *Inga Saman*, which grows rapidly, and casts during the day a checkered acacia-like shade, and closes at night so as not to intercept the dew: until the trees are large enough to give shade, we should recommend the annual planting of castor-oil plants, which will grow to a height of 15 feet in six months, so that during the hot season the young cacao could be overshadowed by it, and at the return of the cool season, the castor oil tree be bodily cut down, and returned to the soil; if this method is adopted, the plants must be vigilantly watched, as a most destructive caterpillar sooner or late developes upon the castor oil plant, when it must at once be cut down, but as this pest never attacks very young trees, it is not a material difficulty. Another common plan is to clear the land, and quincunx the cacao with Liberian coffee, that is to say the cacao planted 15 × 15 with a Liberian tree in the square: this no doubt adds quickly to the value of the clearing, but our opinion is that shade-grown clearing of cacao alone is in all respects more satisfactory, and in the end, more profitable. As regards the distance of the plants apart, it, in a measure, may depend upon the variety selected, and the altitude of the land, but supposing a rich low-lying flat be obtained, and Caraccas cacao be the kind selected, we think 12 × 12 as close as the clearing should be planted. On one fine cacao estate, near Kurunegalla, the proprietor has planted 9 × 9, with the idea of taking out alternate diagonal lines in about five years, after which the remaining trees will be in squares 18 × 18, with a centre tree to each square (or 13·4 × 13·4): in consideration of the value of seed-pods in Ceylon, this may prove to be good policy. It is considered a mistake unless in an exceptionally wet season, to plant *in situ*; the safest method is to put out young *plants*, under shade, in clay pots (the pots are merely long and narrow cylinders); while the young plants are growing in the pots, great care must be observed to keep them from the effects of damp, too much shade, and the attacks of insects, up to a certain stage the Cacao plant is extremely delicate, but once past this it may be considered a hardy tree. We have said that we think 12 × 12 to be the proper distance apart for planting; this will allow three hundred plants to the acre, the approximate cost of opening an acre may be estimated thus:—

Plants	...	...	...	Rs. 25	0
Felling and burning	...	...	...	" 15	0
Lining	...	...	...	" 1	50
Holing 2	...	...	...	" 6	0
Filling in	...	...	...	" 4	0
Planting	...	...	...	" 3	50
				Rs. 55	0

The growth of the plant, once having well started, is remarkable; plants put out when two months old, have grown to a height of four and five feet in the year. It will be necessary at about seven to eight months carefully to remove all suckers; regarding pruning, Simond's model is a "straight single stem up to three feet from the ground, and dividing into two or three as it grows higher: each of these again, divided into two or three branches make up the framework or principal branches which terminate numerously in the leafy branches, regularly disposed into a well-formed head;" practically this means that all matted and weak branchlets are to be removed as well as lateral branches growing at *right angles* to the stem, and a "chick-like" growth encouraged. Should the young trees as, often happens, lean to one side the top should be nipped off, and it will ultimately recover its shape again. The cacao tree, though it will bear at two years, is not fully mature until its seventh or eighth year, and the probability is that pods on trees younger than this contain immature and consequently unreliable seed. A gentleman on whom we place reliance, lately told us that in the London market it is said that we have not yet sent home the higher class of cacao, and we certainly think that more care should have been displayed in its selection. The Venezeula, or Caraccas, Cacao, is the best, although it, according to Simonds, has deteriorated in Trinidad. The pods of this tree are small, but the seeds are more luscious, and globular in form, while the price is very much higher than the common West Indian variety, and we strongly advise intending cacao planters to take care to obtain this seed, especially as we consider that the Caraccas tree will soon become acclimatised here. We confidently prophesy a great future for cacao in Ceylon, and shall be glad fully to ventilate the subject of its cultivation in our columns: experience will no doubt teach us many things not now understood, and it will be well that the results of observation be brought together for the general good.
—*Ceylon Times.*

VEGETABLE IVORY.

AS a substitute for ivory, in the manufacture of certain small articles such as buttons, rings, umbrella handles, &c., where hardness is not so much a desideratum as a fine white color, the use of the so-called "vegetable ivory" is largely increasing, and the trade in the nuts producing the material is becoming very extensive. The vegetable ivory nut is the produce of a species of palm which is met with in a wild state in South America and Africa. When imported into Europe the nut somewhat resembles a Brazil nut, only it is circular in shape, instead of triangular; and they are about the size of a large walnut or small orange. Inside the hard shell is the hard, white "kernel," resembling ivory in appearance. This solid matter, being softer than ivory, and easily carved, or turned in the lathe, and being easily dyed, and less brittle than bone, is largely employed in the manufacture of buttons and similar articles. When exposed for length of time to the air it assumes the granular appearance and the rich yellow, or rather creamy, tint of old ivory. This hard "kernel" is, in its natural formation, of the same nature as the kernel of the cocoanut. The unripe fruit consists of green shell, containing a watery fluid, which, as the nut matures, gradually thickens till it becomes a pulpy mass, and eventually hardens into solid matter. The water, though bitter to the taste is wholesome, and often renders invaluable service to travellers who cannot otherwise obtain water to drink. It becomes sweeter as it thickens, and in South America the pulpy mass is mixed with sugar and water, and largely consumed as a favourite beverage. The tree on which the fruit grows is unlike an ordinary palm, having little or no stem, and drooping downwards, especially when the weak branches are overweighted by the six or seven bunches of nuts—each bunch containing six or seven seeds enclosed in their thick and heavy shells and outer sheath, and weighing altogether from 20 to 24 lbs. Birmingham alone often uses as much as a ton weight in a day, of these nuts, and the annual import into this country (England) amounts to a value of at least £100,000, while equally large quantities are used in France and in other parts of the Continent.—*Hatters' Gazette.*

PAPER FROM BAMBOOS.

THE attention of Forest Officers in Burmah has lately been turned to the possibility of making paper from bamboos. Experiments were made last summer in Clazheugh, near Sunderland, with bamboos sent from Burmah, and the result, it is officially reported, "was an exceedingly strong and even paper, marred only by numerous yellow, scabby looking spots, which, under a magnifying glass, it was easy to see were pieces of hard silicate, the outermost skin of the bamboo, which had not been sufficiently affected by the boiling in the alkali solution." By a more effectual treatment in the caustic solution, it is conceived that these glassy scales would be destroyed; but in any case, if bamboo shoots are used while they are still young enough, there is no glassy skin to be afraid of. Well then, it will be said, cut the shoots young enough, and the difficulty is overcome; but this is not so. After they are cut, they soon harden on the surface. To use them for paper making successfully, it is necessary to work them up while they are still freshly cut, and the inference from this, it will be seen, is that the manufacture can only be successfully carried out in the country where the bamboos are grown. The production of bamboo paper, in fact, is pointed out by Providence as a Burmese industry. The Pegu conservator, who has been employed by the Government to report on this subject, has made some interesting calculations as to the prospects of the undertaking. In order that a factory may be profitably worked, he says it is necessary that it should turn out [illegible],000 tons [illegible] annually. Now it would take 1,000 large green bamboos to yield one ton, or 3,000,000 shoots for each factory. A good bamboo forest can yield 150 young shoots per acre, and would therefore consume the outturn of nearly 32 square miles. But bamboo forests of this extent are available in many parts of the Pegu circle. Obviously it would not answer to depend permanently on the wild growth of Nature, but persons interested are clearly of opinion that it would answer to irrigate bamboo plantations with the view of producing a perennial supply of young shoots, and that meantime a factory could be profitably established at Pegu.—*Pioneer.*

THE PRODUCTION OF SUGAR.

THE production of sugar from the "Imphee" of Africa has engaged attention for some years past in several tropical countries. As closely allied to our "Jowar" or "Janera," it has naturally attracted notice in India, and under the name of *sorghum saccharatum*, its cultivation has been attempted in various districts, but, we believe, unsuccessfully as a sugar yielder. The idea of obtaining sugar from this plant and from maize, in sufficient quantity, or good enough, for public consumption, has been ridiculed by many, more especially in the West Indies. But our indefatigable trans-Atlantic brethren have nevertheless been persevering in their endeavors for some time past, and success is now crowning their efforts. The Indians, too, have taken kindly to the culture and to the extraction of the sugar. The result of trials, so far, has led to the conclusion that sugar of a first-rate quality is obtainable, and that it compares favourably with the best product from sugar-cane grown in the most favourable localities. The cultivation has, it appears, been tried far down in Texas and high up in Minnesota; and that plant has everywhere been successfully raised, and has proved prolific. One great point claimed in its favour is that its saccharine matter is entirely derived from the atmosphere, so that, even though cultivated year after year, there is no reason why it should not increase in fertility. This seems rather doubtful, but those who make the assertion have, they say, good authority for it. The crop of seed is very important for breadstuff. Moreover, good vinegar is obtainable from sorghum skimmings and refuse. The best manures are phosphates, lime, wood ashes and plaster of Paris. An important authority, Professor Caldwell, of Cornell University, is in favour of beet sugar production, and thinks that sorghum stands little chance in competition with beet; but he agrees that there is one advantage in its favor, in the fact that it requires less machinery and less capital. In other words, "sugar can be obtained from the cane, in a small way, for home consumption better than from the beet." Be this as it may, this new industry is regarded as of the greatest importance to the country.—*Englishman.*

THE IMPROVEMENT OF THE POTATO.

WHILE commending the action of Government in its endeavour to introduce a good description of potato in these hills, and thanking Lieutenant-Governor for the liberal grant of money which he has made for the purpose, we would strongly deprecate any importation of potato seed from America. The desire is, we believe, to try various seeds with a view to ascertain and establish those descriptions that give the best results, and with this object seed will be imported from England, Australia, and probably America. We have nothing to say against importing from the two first countries, but we would warn those concerned against having anything to do with seed from America, as it is almost certain to be accompanied by that dreadful pest the Colorado beetle. The ravages of this prolific and almost indestructible insect have been fearful in America. At one time this beetle was an object of great dread on the other side of the Atlantic where the most careful measures were, and are still, taken to prevent its introduction. Nearly every mode of destroying it has been tried with very doubtful success, as the pest is still spreading. We read the other day that Colorado beetles have late been making themselves unpleasantly conspicuous by their proceedings in Westchester country, New York, where they have appeared in alarming numbers. The farmers and gardeners have pressed all their households and all the additional help they can muster into service to make war upon the pest in the potato fields; but it seems likely that in the end victory will rest with the Colorado beetles. The great specific is Paris green; but it requires such frequent application, and is, moreover, so dangerous to use where there are domestic animals that many farmers hesitate to resort to it, and prefer destroying the bugs by means of boiling water. Boys and girls and many other assistants are paid three cents a quart for picking bugs. One smart boy will pick from 15 to 20 quarts of bugs a day. The potato bug is, however, a cunning insect, or it thinks it is. It knows instantly when the vine is assailed, and drops on its back as though it were dead. When the intruder has passed on, it climbs up the stalk, and begins to feed on the leaves again. The effect of Paris green is most instantaneous. The bug drops rolls on its back, gives a few spasmodic kicks, and is dead. Whether it suffers much under these circumstances is a matter of doubt. The farmer generally hope it does but some of them are inclined to think that it does not.—*Darjeeling News.*

THE INDIAN WHEAT TRADE.

THE Indian wheat is a splended grain second to none, full of glutinous qualities which causes it to be in great demand, not only in England but also in France and Italy. It is grown most extensively in all that tract of country by the Nerbudda, spreading in the valleys to Cawnpore in the north, and the Raipore districts in the south, Jubbulpore being as near as possible the centre of the grain districts. The cultivation extends over hundreds of square miles, and although we are accustomed to read of the marvellous crops the virgin soil of the Western States of America and Canada will produce, yet here in India under our very eyes it is grown at a minimum cost, to which no other country can [illegible]. The almost nude native, with a pair of bullocks, and two rough pieces of timber made into a plough, constitute the sole farming stock, and a favourable monsoon the only fertilizer. With these advantages Indian wheat ought to be the largest item of export. The G. I. P. Railway runs through the heart of the wheat country from Sohagpore to Jubbulpore and Nagpore, is in direct through traffic with the East Indian Railway to Cawnpore; the distance is less from Jubbulpore to Bombay than to Calcutta by 168 miles. Yet it is cheaper to send it to Calcutta. The charges are as follows:—

			as	p.	
Nagpore to Bombay,	520	miles	... 11	9	per cental.
Jubbulpore to Bombay,	616	„	... 12	8	„
Jubbulpore to Calcutta,	784	„	... 10	3	„
Cawnpore to Calcutta,	684	„	... 11	0	„

This shows clearly how excessive the G. I. P. Railway chareges are, and although the old excuse will doubtless be urged, of the extra expense this railway incurs through having to traverse the Ghât, yet add 40 miles more to the distances of Nagpore and Jubbulpore for the extra expense of the ghât traffic, and it will still be seen the G. I. P. Railway rates are far in excess of the East Indian. Wheat is an article which has to enter into keen competition with other countries, and the slightest addition to railway charges takes away the small margin of the trader's profit. Our railways charge as much for a distance of a few hundred miles as the Americans do for thousands. For easy reference we quote at par exchange:—

Jubbulpore to Bombay ...	1*s.* 7*d.*	per cental.
Chicago to Liverpool ...	1*s.* 3½*d.*	„

With the splendid facilities of a new Prince's Dock and warehouses our grain trade ought to multiply tenfold, if the zeal which is exhibited in the United States were only imitated in India. It is a matter our Chamber of Commerce ought to take up warmly, for the interests of the Port Trust, and the port and trade of Bombay are most deeply concerned in seeing that the main trunk railway puts forth every energy to foster the wheat trade, instead of charging a prohibitive tariff, and if the object was to check and suppress it.—*Bombay Gazette.*

TREE PLANTING.

THE question of replanting many portions of tropical countries which have become denuded of forest trees, is one which is being taken up in India, and acted upon by the authorities. In the Madras Presidency, in some districts, the collectors call upon the cultivators to plant a certain number of trees during each rainy season, and the question has been seriously taken up, whether it may not be desirable to plant large districts of waste lands, and the roadsides with useful fruit-bearing trees, so that in seasons of food scarcity, if not in times of famine, the people may obtain relief from the produce of the trees. In some districts forest planting or renewing, is taking place in order to maintain the supply of firewood for the railways, in others, to ensure a supply of useful building timber which in many parts of India is becoming scarce.

In Ceylon, apart from the question of timber-supply or effect upon the rainfall, there is the other question in reference to fruit bearing trees viewed either as producers of food for the people, or as a means of improving the public health, where, strange as it may appear, vegetable food is often very scarce; it is an admitted fact that in our towns and chief centres of population the supply of vegetable food is out of all proportion to the number of the inhabitants, and in a tropical country this is particularly to be deplored, as there can be no doubt that the absence of vegetable diet exercises a prejudicial influence on the health of the people.

It should be the effort of our Government to encourage, by all means in its power, the planting out of fruit-bearing trees by the

people, a course which could easily be adopted through the agency of the village Councils ; the same rural organisation which takes account of the repairs of fences and ellas might readily be called upon to see to the planting and keeping in order of a certain number of jack, breadfruit, and other trees, the produce of which would be at the disposal of the population. As we have advocated the propagating and the distribution of useful economic plants by Government authorities, so we would wish to see a distribution of fruit trees through similar agency. This has been attempted in one or two districts, but unfortunately the climate of those localities were ill-suited to the growth of young plants, but there can be no reason why in a large number of districts the rearing and distribution of useful friut trees should not be a most complete success.—*Ceylon Times.*

MANGABEIRA RUBBER.

THE largest quantity and the best quality of rubber has hitherto been imported from the Province of Para, Brazil, and although it has long been known that other provinces of that vast empire contained forests of rubber-yielding trees, these have never been taken advantage of, owing to the ignorance or supineness of the natives. The inhabitants of the province of Hernambuco are now beginning to realise the vast stores of undeveloped wealth existing in their virgin forests, and rubber is being exported from that province, which may, soon rival Para in the extent of its exports of this article. This action is almost entirely due to the exertions of Sanhor Joao Fernandez Lopes, who has spared neither time nor money in his endeavours to improve the agriculture of the province, and to develop its vast stores of natural wealth. This gentleman has issued a circular (dated April 26th, 1880) calling attention to this important source of wealth, and giving practical instructions for the collection and preparation of the rubber, from which the following is extracted :—

"Mangabeira rubber is the most suitable for the springs of railway wagons, tramway cars, and different machines, and for an infinity of other purposes. The process of extracting the milk from the Mangabeira tree is very simple and easy. Each person must be provided with fifty or more small tin basins and a small axe. He should make eight oblique cuts, sloping downwards at a little distance from each other, all round the trunk of the Mangabeira, cutting only the bark, and placing immediately below each cut one of the basins, securing these either with adhesive clay or nails. These small basins will collect the milk that exudes from the cuts, and when full, they must be emptied into a larger vessel. This process should be continued during the whole day, and thus three or four bottles of milk may be collected, according to the fertility of the trees. The cuts should not be deep, as the milk is secreted just below the outside bark ; and a great number of incisions should not be made on each tree, as these may weaken or kill the trees, which has been the case, in some instances with the seringueira, the tree from which the Para rubber is obtained.

"The Para rubber is made in the place where the milk is collected because, in the process of preparation by smoking, there is not time for the milk to be carried to the houses of the collectors ; but here we do not prepare the rubber as they do in Para, but make use of the process introduced into the province of Para, in 1860, by Senhor Strauss, which being much simpler, gives admirable results.

"The process is as follows :—Put a little powdered alum into a teacup full of water, mixing it well, then put a few spoonsful of this solution into a vessel in which three bottles of the milk have been placed, properly strained, to clear it from any extraneous matter. Immediately the milk coagulates, which will be in two or three minutes, the rubber must be exposed to the air on sticks and allowed to drain for eight days. After thirty days, it is ready to send to market in cases or barrels. We have tens of leagues of Mangabeira trees, and long ago we might have made use of this wealth, according to the opinion of Senhor Joaquino d'Almeida Pinto, an intelligent botanist of this province. The seringueira planted here grows perfectly, and there is no lack of different milk-giving trees that might be made useful. The province of Para exported last year three million kilogrammes of rubber, valued at six thousand contos (£600,000.)—*Journal of the Society of Arts.*

THE PAPAYA.

A CORRESPONDENT supplies a Batavia paper with the following particulars of the properties of papaya juice :—

"I have again met with something new about the papaya tree. A short time ago, I reported that in the West Indies, meat is wrapped in papaya leaves to make it tender. Now I see that Frenchmen, on examining the white milky fluid present in the stem, stem fruit and leaves of the papaya, has found that this sap works like *pepsine.* Albuminous substances are consumed by it. It also attacks living tissues, so that the experimenter has tried it on living animals. He has thereupon injected it into hardened swellings which caused great pain accompanied by fever, but very soon made the hard swellings soft after which they were cut into and cure followed. Into a mixture of 4 parts water and 1 part papaya sap he also put a frog, of which after two days, nothing but the skeleton remained. All the flesh had been digested in the bottle just as it would have been in a stomach. After all this it is surprising that now that people know of so many plants which feed on flesh [that of insects, &c.], the papaya which possesses such a flesh consuming sap has no means of catching those insects it might so well feed upon."

OPIUM REVENUE.

Opium Revenue to date compared with the estimate for the year 1880-81.

THE following is the result of five sales of Bengal Opium and 4 months' pass duty on Opium exported from Bombay:—

Total Rs. ...	3,60,15,500	3,74,[illegible]	[illegible],120	...

CALCUTTA BOTANICAL GARDEN.

THE Annual Report of the Royal Botanical Garden, Calcutta, for 1879-80, was read on the 21st ultimo, and the resolution passed [illegible] :—

[illegible] work of remodelling the garden made considerable progress during the year. Additions were made to the ornamental water ; land was levelled and raised ; avenues were opened out and connected with the main roads ; and swampy ground was reclaimed and prepared for planting. The avenue of *Albizzia Paludosa,* which was laid out some years ago, promises to become one of the principal ornaments of the garden. Dr. King hopes to complete the laying out of the garden in two years more. It will then be possible to devote more minute attention to neatness and general maintenance.

2. Experience appears to have shown that *Rhcea* cannot be produced in Lower Bengal as cheaply or as plentifully as was supposed. The plant makes little progress in the cold season, and the stems produced at that period of the year are short and woody. To secure even a moderate yield of well-sized stems deep-hoeing, manuring and irrigation are necessary, and it is only on good land and at a considerable outlay that three cuttings in the year can be looked for. At present the practical importance of this inquiry depends in a great measure upon the result of the attempts to produce an efficient machine for cleaning the fibre.

3. The results of the trial in England of certain coarse grasses of Orissa, to test their suitability for paper-making, are not discouraging. It seems that the two varieties known as *Ranikharia* and *Tiansi* are little inferior to *Esparto* grass, which is so largely exported from Spain for this purpose. The *Sara* grass also appears to be of good quality. Dr. King's correspondent states, regarding *Ranikharia* and *Tiansi,* that "if they can be had in large quantities and at the price of *Esparto,* they might be worth trying on a large scale." Larger quantities will be sent to England for further trial at the close of the present rainy season, and the Lieutenant-Governor requests that the result may be specially reported as soon as it is known. Dr. King explains satisfactorily his failure to examine the long grasses on the banks of the Adjye and Damuda rivers. The Lieutenant-Governor trusts that this work will be taken up during the ensuing cold season.

4. Among the economic plants of which trials have been made in the garden, the *Carob,* the *Eucalypti,* the *Pará* rubber, and the fodder-tree *Symphytum Peregrinum* must now be pronounced failures, and the Lieutenant-Governor sees no advantage in further attempts to induce them to grow in an uncongenial soil and climate. The *Ceará* rubber, on the other hand, promises very well. It is extremely hardy and is readily propagated. The Lieutenant-Governor hopes that it may be possible to tap the trees and test the produce during the current season, Dr. King anticipates that indigo and tea planters in the plains will find it to their advantage to cultivate this valuable and hardy tree. He has made a *Ceará* plantation " in expectation of large demands for young plants and seeds." Dr. King makes the following observations regarding the Guango or Rain-tree (*Pithecolobium Saman*) :—"This wonderful tree grows faster than any hitherto introduced into Bengal, with the single exception of the *casuarina.* It gives a beautiful shade and yields a pod with a sweet pulp, which is greedily eaten by cattle. For avenues, cantonments, squares, and situations where dense shade is wanted, no tree is more suitable than this" The Lieutenant-Governor has already directed the attention of the District Road authorities to the advantage of planting fruit-bearing trees along the sides of the roads, and thus increasing the resources of the district, while promoting the comfort of travellers. The Rain-tree appears to be well adapted for this purpose, and also for the formation of fuel reserves near stations.

5. Altogether 46 Wardian cases of plants were received from different parts of the world and 59 were despatched, against 21 and 24 respectively in the previous year. Dr. King justly points to this increase as evidence of the growing usefulness of the garden in the distribution of exotics. The number of plants sent out in open boxes and pots was 19,447, and of plants so received, 6,055 in 1878-79. In the interchange of seeds there was a large increase, 6,457 packets having been distributed, against 3,972 in the previous year, and 2,448 received, against 1,307. There were also considerable additions to the herbarium. Among the chief donors of plants and seeds were Mr. Bull of Chelsea, M. LeBœuf of Argenteuil, Messrs. Haage and Smidt of Erfurt, and Mr. Van Houtte of Ghent. Those who made the most valuable contributions to the herbarium were Mr. Brandis, Inspector-General of Forests, Mr. Sykes Gamble, Conservator of Forests. Mr. Duthie, Superintendent of the Botanical Garden at Saharunpore, Mr. Fisher of the Assam Forest Department, Mr. Ford of the Hong-Kong Botanical Garden, Major Collett, M. Godefroy Le Bœuf, Archdeacon Hose, and Mr. H. O. Forbes.

Dr. King himself was able to add his own collection made during his visit to the Straits and Java. To all these gentlemen the thanks of Government are due.

6. The garden sustained a serious loss during the year by the death of Mr. Biermann, an officer of much experience and worth. Dr. King also refers to the departure of Mr. John Scott on sick furlough, and the Lieutenant-Governor has, since the submission of this report, heard with regret of Mr. Scott's death in Europe. Mr. Scott had been connected with the garden for seventeen years, and had held charge of the herbarium for a considerable period.

7. The progress of the *Lloyd Botanical Garden*, during the year reflects much credit on the Curator, Mr. Jaffery; several thousands of seedlings were raised and considerable quantities of plants and seeds were received and distributed.

8. [illegible] Lieutenant-Governor again tenders his ack[illegible]ments to Dr. King for the thorough efficien[illegible] displayed by him in the management of the [illegible]

AGRICULTU[illegible]ICULTURAL SOCIET[illegible]IA.

The usual Monthly General Meeting was [illegible] *on Thursday, the 22nd July* 1880.

W. H. Cogswell, Esq., v. p., *in the Chair.*

The proceedings of the last Meeting were read an[illegible]

The following were elected members :—

Mrs. J. G. Macdonald, Messrs A. Springer, W. F. Swan, James [illegible]ray, and Rajah Rajendro Narayan Roy.

The names of the following were submitted for Membership :—

Secretary, Patna Municipality,—proposed by Mr. R. B[illegible]ell, seconded by the Secretary.

W. Mackenzie, Esq., Huttowrie, Belsspore, Tirhoot,—proposed by Mr. G. Toomy, seconded by Mr. G. Swaine.

Mrs. A. J. Hughes, Mozufferpore,—proposed by Mr. H. Stanley Collier, seconded by the Secretary.

Newton E. Jennings, Esq., Engineer, Kimedi Estate,—proposed by Mr. W. F. Grahame, seconded by Mr. H. J. Leitch.

Rejoined.—A. J. Farquharson, Esq., Tea Planter, Gowhatti.

CONTRIBUTIONS.

1. Proceedings of the Boston Society of Natural History, Vol. 19, Parts 3 and 4, and Vol. 20, Part 1, Memoirs of Ditto, Vol. 3, Part 1, Nos. 1 and 2. From the Society.

2. Notes on Tea and Coffee Fertilizer, prepared by David Waldie. From the Author.

3. Memoirs of the Geological Survey of India, Vol. 15, Part 2. Records of Ditto, Vol. 13, Part 2. Memoirs of Ditto, *Palæontologia Indica*, Vol. 1. Part 5. From the Superintendent.

4. Journal of the Asiatic Society of Bengal, Vol. 49, Part 2, No. 1, and Vol. 49, Part 1, No. 1, and extra No. to Part 1 for 1878. From the Society.

5. Plants and seeds from the Nicobars. From E. H. Man, Esq.

6. Seed of the yellow flower variety of the Dhak (*Butea frondosa.*) From J. V. Sturt, Esq., v.p., Municipal Committee of Mau, Rampore. Mr Sturt remarks that it is a rare variety, and very pretty seen in blossom alongside of the common or scarlet variety.

7. Seed of *Millettia ovalifolia*, from Rangoon. From R. Rowett, Esq. This is a handsome tree and supposed to furnish the "Moulmein Rosewood."

8. Seedlings of *Amherstia nobilis* and plantain shoots from Moulmein. From C. Ady, Esq.

9. A quantity of Mahogany seed. From Dr. G. King.

10. Bulbs of *Eurycles Cunninghamii* and seed of *Acronychia Baueri*. From L. Bernays, Esq., v.p., Acclimatization Society of Queensland.

REPORT ON NEW PLOUGHS.

A second report of a Sub-Committee of the Council (Dr. S. Lynch, Mr. W. H. Cogswell, and Baboo P. C. Mittra) in respect to trial of certain ploughs, was read as follows :—

Your Committee presented their preliminary report at the general Meeting in March last on a plough submitted by Mr. Martin of Etawah, when it was resolved that another trial be given to this and any other ploughs submitted for competition, when the rainy season had fairly set in.

Accordingly, on the 23rd June, your Committee met again at the Society's garden, when the following ploughs were arranged for trial :—

1. A combined plough from Mr. Martin, of Etawah, single handle, weighing about 12 seers, selling price, Rs. 3 at Etawah, in Calcutta, Rs. 4.

2. A plough from Mr. Crawley of the Cawnpore Model Farm, made of wrought iron, weighs 14 seers, said by the maker to plough 6 inches without any pressure whatever being used by the ploughman, the cost of making will not exceed Rs. 5, single handle.

3. A plough from the central prison, Benares, double handle, and no beam, cost Rs. 15.

The land on which the trial was made may be termed grass land. It had never before been prepared for any purpose, the grass was in most parts short and close, nowhere long and jungly. Sufficient rain had fallen to render the ground soft and practicable for ploughing purposes.

The cattle employed were the ordinary village plough bullocks.

With respect to the Benares plough (European in all respects, except in the absence of the beam,) it was found to be beyond the powers of bullocks of the above description owing probably to a defect in the shape, the soil clogged at the shoulder of the mould board, increasing the draught whilst the soil was not turned over; when it was attempted to increase the depth of the furrow, the heel of the plough was lifted off the ground. This is one of the results of the absence of the beam. Another is that the ploughman's command over the plough during heavy work is lost owing to the absence of leverage. The body of the plough is a heavy inert mass in the ploughman's hands. The width of the furrow with this plough is about six inches. The depth could not be fairly stated from the trial.

This plough might go through light soil previously worked without any difficulty.

The Cawnpore plough, in like manner, cutting a furrow of six inches in width by above four inches deep, was heavy in draught, and failed to invert the soil. The mould board was clogged all the time.

The plough from Etawah (Martin's) performed its worked efficiently. It shewed a light draught well within the power of the little Bengali bullocks; it turned the slice completely over, making a furrow of a depth of three inches, with a width of $4\frac{1}{2}$ inches. This plough, whilst it resembles most nearly the native type in construction and cost, makes a close approach to the European plough in the mode in which the work is turned out. But there is the radical fault in this and other ploughs with fixed beams, that at the moment when the work is heaviest, the heel of the plough will be drawn up and the point depressed to such an extent as to tax severely the strength of the ploughman.

Resolved that copies of the above report be sent to the parties interested.

RHEEA FIBRE.

Submitted certain papers [illegible] the above forwarded by the Secretary to the Government [illegible] Bengal, with a sample of Rheea fibre referred to therein. Mr. Mackenzie adds: "that the Lieutenant-Governor would be glad if he could be favoured with the opinion of the Society as to the commercial value of the fibre and its suitability to the Indian and home markets."

From Messrs. Burrows, Thomson, and Mylne of the Jugdispore Estate, Beheea, dated 8th April 1880.—"In reference to the recent competitive trials at Saharunpore of machinery for extracting the fibre of the Rheea plant, it may be interesting to his Honor, the Lieutenant-Governor, to know that the fibre has been prepared many years ago at Bhagulpore by some families of the Dhanook caste for the silk-weavers there.

We were aware of this, and at the time of the recent competition sent to the President of the Government Committee, sample of Rheea fibre prepared by the Bhagulpore method, with a description of the process.

It was also suggested that this process might be beneficially carried out by the female members of poor Rajpoot and Brahmin families who are not allowed to appear in public or engage in field work. There are great numbers of such families whose women have literally nothing to do.

Clean Rheea fibre brings high prices in Europe and is valuable as compared to its bulk.

The plant is perennial, and the cultivation similar to that of sugarcane without the labor and expense of yearly planting. The roots properly attended to will give three or four cuttings yearly in this part of the country. If left in the open field cattles don't graze it. These are desirable qualities in the estimation of Rajpoot and Brahmin cultivators.

We have procured roots from the Saharunpore and Calcutta Government gardens, with the intention of doing what may be possible, to introduce a valuable industry among the Rajpoot and Brahmin families, resident in the villages of the Jugdispore Estate.

A small sample of Rheea fibre from plant grown here and prepared by the Bhagulpore process, is herewith enclosed for the inspection of his Honor the Lieutenant-Governor."

From the same, dated 19th September 1879, *to the President of the Rheea Committee, Saharunpore.* RHEEA FIBRE.—The method for obtaining this fibre, practised by certain natives of Bhagulpore of the Dhanook caste some eight or ten years, or still further back, is generally as follows :—

The site of the little factory is chosen, if possible, near a stream of soft water, as the process is one of slow boiling or simmering, and beating in combination with washing.

The factory plant is an earthern or other pan or boiler, and two notched boards, such as *dhobies* use.

The work-people—two men, two women, two boys.

The boiler is charged with water sufficient to cover the shoots proposed to be dealt with, and to it is added about 10 chittacks *sujjee-muttee* for a maund of plant placed in the boiler, the whole is then allowed to simmer or boil slowly for half or two hours.

The shoots are then taken by or handed to the nearest man with a notched board before him (the boards being placed near by or partially in the water *dhobi* fashion) in such portions as can be held firmly between his two hands; he continues to dash it against the board, washing it at the same time, thus clearing each end alternately of the wood and portions of the bark and gum. The handful is then passed on to the second man with a similar board who beats and washes it in the same way to free the filaments still farther from gum and bark.

After this it is taken by the boys back to the boiler to be again slowly boiled or simmered for about an hour. It is then again beaten and washed by the two men as before till the gum is removed and the filaments are free.

The two women now take charge of it to be dried, beaten, and drawn or carded till it is in the condition of the accompanying samp e, but much whiter.

A maund of shoots per hour can thus be easily worked off, which, if its filament is in the plant in the proportion of $2\frac{1}{2}$ per cent., will be one seer

of fibre fit for spinning by the native hand-method or for the carding machinery sent to Europe. If the percentage of filament in the plant is over 2½ per cent., the outturn will be increased in proportion, while no addition is made to the cost.

By adding half the original quantity of *sujjee-muttee* to the water in the boiler, it may be used again, afterwards the water should be changed.

We propose introducing the domestic cultivation of the Rheea plant and preparation of fibre to the people of the villages on the Jugdispore Estate in the hope that it may make a considerable addition to the family earnings especially to high caste families, whose women as a rule *purda nashin*, and to whom it seems the preparation of the fibre would be a profitable means of passing time otherwise useless. The plant being perennial and handy, would require little care from the men beyond perhaps loosening the surface and weeding every two months and giving some manure twice yearly.

Should any simple machine be required or found to be beneficial, we have reason to believe that the want will be met by two small rollers on the principle of the native *chirkee* or cotton gin roughed on the surface and working at different degrees of speed; this has been found to loosen and partially remove the bark, and to some extent freeing the filaments from the gum or gluten by the drawing or triturative motion of the rollers so adjusted to each other.

In addition to our memorandum on Rheea fibre, handed to you yesterday, we will be glad if an opportunity can be given during November and December next of testing on a reasonable large scale the Bhagulpore method of preparing Rheea fibre, at or near the Botanic Gardens, Calcutta, where, we believe, a considerable quantity of Rheea ...

Report by Mr. W. H. Cogswell.—I consider this sample of Rheea to be one of the best that has been submitted to me for a long time past, as regards its color, cleanliness, and soft silky fibre, and its comparative freedom from gum and mucilaginous matter. The fibre, has not been destroyed by chemicals, as is so frequently the case in many processes, and I think but very little injured or weakened in its strength under the simple method is said to have been adopted in its preparation. It is excessively short, owing, I think, to excessive hackling or combing, and a great waste must have been the consequence. Its value in consequence will be materially lessened. It is, however, admirably adapted for spinning, and I would recommend that in the absence of spinning and weavingsteam machinery a sample of cloth be prepared by hand. It is beyond all doubt, of great commercial value in Europe, for blending with silk fabrics, and I advise that a good large sample be sent to England to be properly and carefully valued, which, I think, it is quite impossible to arrive at in this market.

Note by Mr. W. Stalkartt.—I quite agree with all Mr. Cogswell has written above.

Report by Mr. S. H. Robinson.—I agree with Mr. Cogswell's remarks: but before sending the sample to England for valuation in the home market, I think Messrs. Thomson, Burrows, and Mylne might be asked at what rate it is usually sold in the Bhagulpore district, and the rate quoted to the English dealers to whom it is proposed to send the sample.

HINGLI TOBACCO AND ALOE FIBRE.

Submitted certain specimens of the above, obligingly forwarded for the inspection of the Meeting, by Mr. H. H. Locke, Secretary to the Economic Museum, with the following note thereon :—

Here are the samples of—

1. Hingli tobacco.
2 and 3. Aloe fibre, combed and uncombed.
4. And matting made from the Aloe fibre,

which you thought your Society would like to see to-morrow.

I subjoin some short notes about these things :—

The Hingli tobacco was received from the Magistrate of Nuddea. It had been exhibited at the Ranaghat Exhibition in January last, and was sent to us at the end of April. On the 10th May it was thus reported on by a Calcutta expert :—

'A very good sample of Hingli tobacco. Sweet and well cured, comparatively free from stem, worth in Calcutta to-day (10th May) Rs. 9 to Rs. 9-8 per maund, or say Re 1 more than good ordinary Hingli.

'Owing to the weight of stem natural to this quality of tobacco, it is not suited for European markets.'

The Aloe fibre and Matting comes from the Hazareebagh Jail. Dr. Cobb the Superintendent, writes concerning the Matting that

'It is of very superior quality; is everlasting in wear, and looks well to the last. Is especially suited for passages, or the aisles of churches or public buildings; ship and steamer saloons, &c.'

Its price is Re. 1-4 a yard. Some excellent samples of lines and twines made from Aloe fibre, were also sent by Mr. Winter, the Jailor of the Hazareebaugh Jail, for transmission to the Melbourne Exhibition. I am sorry I cannot send you samples of these, but the speci mens I received were too small to admit of portions being retained for permanent deposit in this Museum, and the original samples have been despatched to Melbourne.

SEED POTATOES FROM MELBOURNE.

The Secretary drew attention to ten cases of seed potatoes just received from Melbourne, through the kind intervention of Messrs. Anderson Wright & Co. These potatoes are in excellent sprouting condition, but having arrived too early in the season for Bengal, it was agreed to distribute them to residents at Darjeeling and other hill stations, and ask them to send down a portion of the produce for trial ... weather.

The best acknowledgments of the Society ... Anderson, Wright & Co., for their ...

and about sixteen miles south-west of Ellore in the Ganjam district, But there are six other places in the same locality where diamonds are, or have been found. The names of these places are Mallavelli, Alkur, Parthenipadu, Pra'alli, Wastapille, and Kodavetti Kall. Easwick relates that :—

"The hollow flat, where the diamond pits are, is a low, dry, gravelly plain, but which has the appearance of having once been a lake. Through this plain no steam flows and the pools, in its lower part, dry up in March, ... in which excavation may be commenced, and not before. The pits ... in general excavated at the north end of the bank that surrounds ... hollow. The deepest are not more than 12 ft., and whatever the depth, a hard mass of rock is never reached. The strata penetrated are—first, a grey, clavey, vegetable mould, about a foot or two thick : below this an alluxium of the following pebbles, rounded by attrition : sandstone quartz, siliceous iron, hornstone, carbonate of iron, felspar, conglomerate sandstone, and a prodigious quantity of concretionary limestone. The diamond is never found imbedded, or in any way attached to any of the pebbles, but always loosely mixed with the other little stones. The detritus, forming the diamond stratum, must have proceeded from the hills to the North, the only hills, in fact, near the place. They are the continuation of the standstone range, which extends east from Banganapilli, Knodapilli, and Mallavelli, in all of which localities the matrix of the diamond is a conglomerate sandstone."

From this locality, the world has been supplied for centuries with ... of the purest ... Mr. The diamond which Mr. Pitt, the Governor of Madras, ... ather of the first Earl of Chatham) obtained, and which has been long known as the Pitt diamond, was found in Golcondah. It was taken by the Governor to Europe and sold to the Duke of Orleans for £130,000. It decorated the hilt of Napoleon's sword, was captured by the Prussians at Waterloo, and it now belongs to the King of Prussia. It wei hs in its cut state 136¾ carats, and is said to be unrivalled in its limpidness, and its form. The Kohinoor, the Mountain of Light, was found—according to Hindu legend—in a Golcondah mine. It originally weighed 900 carats, but has been reduced by cutting to 123 carats, and is now valued at £120,661. It is now the personal property of the Que n. There is fair reason to suppose that the wealth of the Eastern region has not been exhausted, and that the appliances of modern machinery directed by men of science may bring to light gems that have not been discovered by rude native processes of search. A rumour has reached us that a scheme is afloat for developing the diamond resources of the Golcondah locality. That it may be worth while to prospect for diamonds is shown by the remarkable facts that the value of Cape diamonds transmitted through the Post Office in the six years 1873-79 was no less than £16,409,417. Besides these gems a large number went to Europe in the custody of the owners, or as freight, and it is likely enough, making allowance for under-valuation that the total proceeds of the Cape mines approximated closely to twenty millions sterling in the seven years. The best Cape daimond is a slightly yellowish, and certainly, inferior gem to the best Indian diamond ; yet so great is the demand for the jewel that the world bought the inferior article to the above extent. This seems to indicate that gems of the first quality are scarce, and that if Golcondah should answer the expectations of some sanguine individuals, a great addition may be made to the exports of the country.—*Madras Ma il.*

IRON ORES IN MADRAS.

WE quote the following from that interesting and useful book published by Government, "Standing Information regarding the Administration of the Madras Presidency," it will be seen that there are iron ores there, which only require enterprise to make them of great use to us :—

Some remarkable deposits of magnetic iron ores are found in the Salem district. The ores occur in large beds of from 50 to 100 feet in thickness, and the out-crop may be traced for miles. On one hill, six miles from Salem, there are five bands of magnetic iron from 20 to 50 feet thick. In 1825, Mr. Heath of the Civil Service. obtained a Government advance and formed a company to establish iron works at Porto Novo near Cuddalore, at Palampatty near Salem, and at Beypore on the West Coast. At the last place the iron was to be obtained from the laterite. The Porto Novo works were begun in 1833, and those at Beypore some years later. The Government gave their aid, but the experiments failed. The causes assigned were the distance of the works from the source of supply, scarcity of charcoal, and various other practical difficulties. Several companies took up the matter, but with no final success. The information that is available regarding native working in iron will be found under the head of Manufactures. Though not of such extent or thickness, yet still of sufficient importance to be of considerable value in any further opening up of the country by rail or canal, are some great veins of iron-ore in the Kurnool district, which occur in the Gunnygull and other smaller ridges near Ramallakota some 12 miles south of Kurnool. The ore is the grey micaceous or specular iron oxide and is very rich. Old workings on pits are common all over the ranges, showing that much ore has been extracted, but only one or two furnaces appear to be worked now at intervals during the year. The great drawback to the evident richness of this iron field is the scarcity of fuel, which however might be obviated by the conservation of the jungle in the adjacent hill ranges.

We have also lead and copper ores, as will be seen from the following paragraphs which we extract from the same publication :—

Lead ore occurs in the Nallamullay range of the Cuddapah district where it was worked very largely in ancient times ; but although the indications of its extent and richness are fairly good, no continuous or, systematic attempt has been made by Europeans to re-open the mines. Mr. P. W. Wall, the Mineral Viewer to Government in 1858, explored these mines, but did not report very favourably of them, though he seemed to consider the percentage of silver large. The latest assay (1879, by Mr. Mallett of the Geological Survey of India) of a small specimen, gave 78 per cent. of lead, containing silver at the rate of 22oz. 7dwt. to the ton.

Copper ores are met with in the Cuddapah, K[illegible] Nellore districts in old workings, the best indications being in the latter district, near Gunulpenta, where, some 40 years ago, they were important enough to attract European enterprise, but without any successful result. Within the last year, however, attempts are again being made by a Madras Mining Company, both in this region and in the Cuddapah district, to work these and the lead ores. The Nellore mines are considered by Mr. King, the Deputy Superintendent (for Madras) of the Geological Survey of India, not to have been adequately tried, the traces of ore being frequent and promising, while the old attempts have been carried on by incompetent men met by the usual temptations and insalubrity of the climate.

IRON ORES IN CENTRAL INDIA.

As a means of famine prevention, the development of industrial enterprises is to be ranked with, if it should not take precedence of irrigation works and railways ; and among such enterprises no[illegible] perhaps, holds out fairer prospects than that which [illegible] so largely to British prosperity—iron manufacture.

Everybody knows that there is iron ore in many parts of India, but it is not generally known that in Central India there are ores of that metal of the best quality.

The Central India iron-ores are remarkable at once for their purity and their richness. They are chiefly red iron ores and magnetite, containing sometimes manganese, but there are also brown iron ores and siliceous hematite. As all these ores occur in enormous quantities on the surface of the ground, the erection of costly mining works, which is elsewhere necessary, is here not required. Owing to the difficult treatment required for the magnetites, the native iron-makers prefer the soft red iron-stones of a laminated texture, although the former contain a larger percentage of iron. The brown iron ores and the siliceous hematities are used by them only very exceptionally.

Before showing how the Indian iron ores may be utilised without prejudice to English interests, we will give an analysis of the iron ores of Central India, together with some other details.

The magnetites contain 71 per cent. of metalic iron (or 69 per cent. oxyde, and 29¼ per cent. protoxyde of iron), the red iron ore from 65 per cent. to 69 per cent. of iron (or 91 to 98 per cent. of oxyde of iron), the brown iron ore 45 to 55 per cent. and the siliceous hematites 40 to 48 per cent. of metallic iron. The few impurities of these ores are small quantities of quartz, clay, and manganese and exceptionally some lime; of sulphur there are but few traces, of phosphorus none—at least none have been discovered in the red iron ores and in the magnetites.

So much has the exceptional purity of these ores struck observers that somebody, writing of them in a public paper, some time ago maintained that they were pure iron, which is incorrect ; the richest iron ores can never contain more than 72 per cent. of metallic iron. Iron always occurs in nature combined with oxygen, the lowest degree of oxydation being in magnetite. Pure iron might perhaps be said to occur in meteors, but here also it is combined with nickel from 3 to 8 per cent. We know of no ores in the world which are fully equal to those of Central India in purity, in richness, and quantity over a given area.

In general the European iron ores contain only from 30 to 35 per cent. of metallic iron, therefore half only that contained in the red iron ores and in the magnetites of Central India. How great a value is put on pure and rich ores by iron makers may be learned from the circumstance (which should be made widely known in India) that vast quantities of such ores are yearly imported into England, France, Germany, and Belgium, from the south of Europe and more distant countries.

The iron ores of Central India containing, as was said before, no phosphorus, and little manganese, are suitable for the production not only of bar iron but notably also of steel, and especially of Bessemer cast-steel for rails. It is well known that the amount of phosphorus in the ore determines its fitness for the Bessemer process; and if it exceeds ½ per cent., the steel cannot be converted into rails, which are now generally made of Bessemer steel. Again, ores containing manganese are known to be especially useful for the production of steel for cutting tools. Equally suitable are the pure red iron ores of Central India, containing manganese, for the production of "Spiegeleisen" (specular cast-iron) a kind of pig iron, which is added to the iron in the Bessemer process, and in cast steel crucibles. Great quantities of this article are exported from Germany and Austria, and the price of it is 60 per cent. higher than that of ordinary pig iron. The same is the case with an article called in the trade *acier sauvage* (wild steel), also a kind of pig iron, containing a very small quantity of carbon. This is exported at high prices, from Styria in Austria to England, France, and Belgium, for the manufacture of ductible iron for wire. Now "Spiegeleisen" and *acier sauvage* can only be obtained from the *purest* iron ores, and of these there are inexhaustible mines in Central India. Here we have then a most valuable raw material for exportation which would not interfere with England's commercial policy as regards India, which has hitherto consisted in the principle of taking India's raw produce and returning it to her in the shape of manufactured goods.

Should the art of iron making in the course of time be so far developed as to furnish us with an economical process of making [illegible] or steel direct from the ore, that is to say, without the introduction of the blast furnace and fining process, then pure ores would greatly increase in value and become eventually a most important article of export from India.

The following explanation of the present system of iron making will show the importance of the exertions which are now being made towards the obtaining of iron by a *direct* process.

The object of the blast furnace process is, first, to free the ore from oxygen, then to induce carbon into the article so obtained, and finally, to melt this compound. The product of the blast furnace is thus iron with a greater or lesser percentage of carbon, called pig iron. The next, namely, the fining process, has for its object, on the contrary, the freeing of pig-iron from carbon or the production of a metal free or nearly free of carbon. To the uninitiated the question will at once present itself why these opposite processes are followed—why the reduced ore, *i.e.*, the ore freed from oxygen, is not melted down direct into iron [illegible] blast furnace instead of first infusing it with carbon, and then [illegible] by the expensive puddling or Bessemer process. [illegible] difficult to melt down pure [illegible] 1,700° [illegible] [illegible] of [illegible] 300 to 500 [illegible] to attain, both as [illegible] furnaces. The second cause [illegible] impure state of iron ores, [illegible] and sulphur. Opportunity and time [illegible] to these impurities, and this is done by the [illegible] manipulating of the stuff in the so-called fining process.

From this [illegible] the reader will easily perceive that, in the [illegible] magnetite and red iron ores, in which we have to deal with either very small or inappreciable quantities of impurities, the question of producing pure iron or steel by a *direct* process is reduced to one for the science of heat to solve. It is a question, in fact, of producing 1,700° centigrade of heat economically. The solution of this question is approaching. The efforts of Siemens, Dupuis, and others in this [illegible], if they have not solved this problem, have at least paved the way to its solution. But it may be objected that the best iron ores and the largest quantities of them in Central India are of no avail, as there are no coals there ; the reply to this objection is that there is ample wood available. Again it may be objected, as was indeed done a short time ago by a writer in the columns of a daily contemporary, that making iron in India with charcoal has been tried and has failed. It is well known, however, that excellent iron has been made in India, for centuries, with charcoal. Those also who know anything of the iron trade, know that vast quantities of iron are made in Sweden and Styria, both for home consumption and for export with vegetable fuel. It cannot be that the price of charcoal in India is an obstacle since it is about three times as high in Styria, for instance, as in India; neither can the failure have been caused by the experience of charcoal making bad iron, for the reverse is well known to be the case. The true cause is not far to seek; it can have been due to nothing else than to ignorance or bad mechanical arrangements, or bad management, or dishonesty, and very likely to all these combined.

It is on the question of vegetable fuel *versus* mineral coal that the future iron industry of India will depend, and in a future issue we shall probably examine the question in detail.—*Englishman.*

BURMAH GOLD.

Some specimens of gold from the gold washings near Shwegyeen with parcels of the soil or sand from which gold is washed, were forwarded in 1853 for examination to Dr. Oldham, the late Superintendent of the Geological Survey of India. The result of that examination was as follows :—

One parcel, said to be the surface-soil, was found to be a gravelly sand, consisting principally of small grains of quartz, minute flakes of bright-colored mica, generally of a golden tint and of pebbles of various kinds of metamorphic and crystalline rocks. A few small crystalline pieces of topaz occurred in the sand, and one or two minute red garnets were also found. Mixed with this, sand was found in small quantities and in minute grains some magnetic iron sand and a few acicular crystals of schorl. The sand in this parcel did not altogether amount to the fifth part of a cubic foot. By simple washing, it yielded 0·75 of a grain of gold in minute flakes. The residue of the sand was then successfully agitated with mercury in order to obtain by amalgamation any particles of gold which might have been too minute for mechanical separation. By this process 0·20 more of a grain of gold was obtained. Consequently, from less than the fifth part of a cubic foot of soil 0·95 of a grain of gold was extracted.

The second parcel contained a yellowish ferruginous sandy clay, looking as if it were the result of the decomposition of the upper portion of the rock *in situ*. This clay was reduced to a fine state of division and carefully washed—the sandy portion, consisting chiefly of ferruginous quartz grains, being separated. The residue was carefully examined ; but no traces of gold were discovered. The fine, slightly sandy clay, which remained after washing, was considered well suited for the coarser kinds of pottery ; it stood the fire well, and it was sufficiently tenacious to admit of being readily moulded.

The specimens of gold consisted of varieties ranging from dust of the finest kind that could be mechanically separated, to small nuggets. Two specimens described as "purchased at Shwegyeen" very well illustrated the mode of occurrence of the gold in its Native State, imbedded in quartz, while the other specimen showed that the general form in which it is found in these washings is in small rounded flakes or flattened plates of various sizes. This gold was proved to be of considerable purity—yielding on careful analysis 9,200 of gold and 80 of silver in 100 parts.

This result, although tolerably accurate was to be taken only as approximative. It was, however, sufficient to show that the Shwegyeen gold was fully equal in value to the average quality of Australian gold.

The occurrence of gold of fair purity being undoubted, the question remains as to the quality in which it may occur, and the probability of its yielding a fair return. If the specimen of auriferous sand were to be taken as a fair average sample of the kind of soil and of the quantity of gold contained in it, it followed, according to Dr. Oldham, that, as nearly a grain of gold was procured from about the fifth part of a cubic foot of soil, a cubic yard of the same sand should afford about 135 grains of gold, or, if the portion obtained by amalgamation, namely, 0·20 of a grain, be excluded, the yield by washing alone should be 101·25, or say, on an average, 100 grains of gold for each cubic yard of the sand washed. This sand being surface soil, and, therefore, easily accessible without the labor of sinking pit or [illegible] cost of keeping such pits open, two men could with gr[illegible] wash a cubic yard of soil, daily obtaining [illegible] [illegible] grains of gold between [illegible] [illegible] 100 [illegible] day's [illegible] and the difficulty is overcome [illegible] each man [illegible] harden on the surface. per diem—a ro[illegible] necessary to work utterly insufficient to [illegible] this, it [illegible] Oldham, however, qualified [illegible] out yield of the auriferous soil would [illegible] in character and in richness according [illegible] the deposits may have been formed. The [illegible] ever, of the greater part of the Malayan [illegible] to Arakan northward, so far as known, indicat[illegible] [illegible]ence of auriferous deposits throughout the whole [illegible] of the central ranges of high ground. The ascertain[illegible] existence [illegible] in more than one locality in Shwegyeen and other par[illegible] of the Tenasserim as well as the association in these [illegible]calities of magnetic iron sand with the gold (a mineral so constant [illegible] accompaniment of gold as to have earned among miners the nam[illegible] of the "mother of gold") appeared to Dr. Oldham to confirm this reasoning from analogy. The auriferous deposits he had referred [illegible], he was convinced, occur at intervals throughout the whole r[illegible]ge, and that locality then would prove to be very rich.

Judging from the rude manner in which the gold wa[illegible] washed by the people, Dr. Oldham thought that fully one-half [illegible] the entire amount of gold contained in the sand was in a probability irretrievably lost. In his opinion it was extremely desirab[illegible] that some more efficient, yet simple, apparatus for separating the go[illegible] by washing and also for amalgamating it with mercury might be in[illegible]roduced into the district, when the greatly increased quantity of gold [illegible]hich would be obtained by the use of such improved appliances, would quickly lead to their general adoption. The gold washings are, howe[illegible]r, still conducted in the same rude manner as before.

We have been induced to reproduce the above, written during a late agitation on the subject as it bears upon what is now being talked of about the gold capabilities of this province, the "Avrea Regio" of Ptolemy, and the *Survarna Bhumi* of old.—*Eurasian* (*Rangoon*).

[illegible]TICULTURAL [illegible]A.

[illegible] *on Thursday, the 22nd* [illegible]

FORESTRY.

A FOREST Conference was held, on Saturday 31st July, at Poona in the Council Hall. There were present the Governor of Bombay in Council, the Revenue Commissioners, and Mr. A. F. Shuttle-worth, of the Forest Department. No definite policy was decided upon. Sir James Fergusson is said to be well versed in forest matters.

WE learn that the Wynaad Planters' memorial to Government for the construction of a line of Railway from Beypore to Mysore has received the cordial support of Government, as both the Chief Commissioner and the Consulting Engineer for Railways consider the line would yield a fair revenue, and would tap the forest resources of Mysore.

REBOISEMENT.

THE Forest Commissioners of France addressing the Chamber of Peers in 1827, thus expressed themselves:—"The denudation of the hills excites everywhere universal complaints. Their sterility through the carrying away of the vegetable earth which was retained by the trees, the diminution of springs, the augmentation of superficial water, the formation of torrents which overwhelm properties situate below these elevated places, these are the consequences of the wood-cuttings made there, and it will be against these denudations that the administration will arm itself with severity." Accordingly laws were enacted to remedy the danger which had been created by the denudation of mountain ranges, hill, and drainage slopes. And the forest administration have with great success conducted operations more especially under the laws of 20th July 1860, and 8th June 1864, for the reclothing with vegetation of the highlands upon which the great rivers of France—the Loire, the Garonne, and their several important affluents have their sources. Thus under the able and energetic working of a staff of accomplished officers supported by an enlightened Government, the re-afforestation of French Alps, the Pyrenees, the Cevennes, the mountains of Auvergne, and other water-sheds of the country has become a reality in some cases surpassing all expectation. So successfully indeed, has the reboisement of several of the mountain ranges been accomplished that in the Paris Exhibition of 1878, the Government exhibited models, photographic views, maps, drawings, and plans, illustrating the effects of the forest denudation, the different kinds and classes of works adopted for defence against torrents and for eventual reboisement, and finally the beneficial results of these measures. This collection attracted great notice and created profound interest. One set of photographs illustrate the general aspect of the mountains above what was once, and not so very long ago, one of the most fertile valleys of *la belle* France, and they show how the torrents have scoured and cut up the mountain sides, have deprived them of their protecting vegetation, have swept away the soil, and have carried the soil into the valley to cover fields and smother cultivation, and to fill tanks and reservoirs and wells; how the torrents rush down-ward in uncontrolled fury from the rock exposed slopes to interrupt commu[illegible], [illegible] destroying bridges, roads, railways, &c., thus converting [illegible] civilization into waste, prosperity into desolation, to endanger life [illegible] filling rivers and streams with sudden and fierce floods which sweep away homes lands and farms, and even inundate and destroy towns. The map of Embrunais shows the public road covered with blocks of stones brought by the torrent from the overhanging slopes. A second set of maps and designs illustrates the different kinds of defence works adopted to fight against torrents and provide for the introduction of reboisement. These works consist of masonry dams across torrent beds, *barrages* or weirs—*contro-barrages* or buttresses—living weirs of stakes wattled with willow branches, dams of earth, dams of dry stone, and many other similar contrivances designed with great skill and ingenuity. Some of these defence works cost a great deal of money; for instance, in the plan of the torrent of Bourget we see a solid stone wall built with hydraulic current about 10[illegible] feet long, 25 feet above the torrent bed, having 15 feet of underground foundation and 8 to 9 feet thick, at a cost of £650. Other sets of views [illegible] and sketches [illegible] changes which have followed the establishment [illegible] works, how vegetation has gradually resumed its place, how torrents have gradually disappeared, and finally, how forests begin to cover the mountain slopes. Views of Jabouret show how in less than thirteen years a perfect revolution has taken place. Formerly there were great slopes of blackish marl always slipping away; now they are all covered with trees and with a dense growth of herbage suitable for fodder. Numerous small ravines, once forming so many channels to swell the floods in the main torrent, are now filled up, and the whole basin of the torrent is completely restocked with trees, and this once renowned torrent is now a permanent and harmless stream. The maps confirm what other evidence has established:—*First*, that forests protect the soil so that torrents cannot form and erode it. *Second*, that the removal of the forest renders the soil subject to torrent action. *Third*, that the destruction of forests has entailed and does entail barrenness and aridity in parts of the country affected, and which were renowned for their fertility. *Fourth*, that along with woods, springs, and rivulets disappear and cease to water the parched land *Fifth*, that the actual temperature of a country is by the destruction of its forests very sensibly increased. *Sixth*, that the rain gradually washing away the vegetable earth from the sides of denuded hills condemns them to sterility, while these latter, no longer able to retain and regulate the flow of water that falls in their slopes, are scored by deep gullies formed by impetuous torrents, while the beds of rivers are at one time dry, and at another filled by sudden and short lived floods. *Seventh*, that even while torrents are in existence, planting, and restoring vegetations to the slopes moderate, the violent action of the torrent and ultimately extinguish it. *Eighth* that when torrents have been extinguished, the renewed destruction of the forest may re-awaken them into dangerous activity. Thus it will be seen that the importance of placing all the hills, mountains, and drainage slopes of a country under strict forest protection, cannot be exaggerated. Nature clearly intended that her reservoirs for the storage of water for supply to and for the irrigation of the cultivable lands in the valleys and plains should be placed upon the higher levels of the country, and where these natural reservoirs have been thoughtlessly and wantonly destroyed by man, there has Nature always exacted a terrible revenge But forests and trees upon the plains, also, more especially in a tropical climate, exercise equally important influences on the condition of countries, and well may it then be said that not only the prosperity, but the very safety of a country is dependent upon the proper conservation of its forests. So great value and importance does Austria attach to her forests that they are called the sources of the nation's wealth; while in Germany it is the natural belief that as trees are rooted in the soil, so is the welfare of the German people with its roots bound up in a perfect system of forestry.—*Bombay Gazette*.

GARDEN.

LARGE trees, especially tall poplars, placed near a house may serve as very efficient lightning conductors, but always on the indispensable condition that there is no well or running water on the opposite side of the house, for in that case the electric fluid if it struck the tree might pass through the building on its way to the water. In 1894 a house at Lancy, almost in contact with a poplar on one side and a marsh on the other, was set on fire by lightning, and the path of the electric fluid from the point at which it left the tree across the roof of the building to the marsh could be distinctly traced. Hence, in erecting lightning conductors, it is desirable that their lower extremities should terminate in a stream, a well, or a piece of damp ground.

A FERTILIZER FOR STRAWBERRIES.

An experiment made last year by myself may not come amiss at this time with those who grow strawberries. I procured a half hogshead, filled it with rain water, and put into it one-quarter pound ammonia, and one-quarter pound common nitre. When the strawberry plants were blooming out, I gave them a sprinkling of the solution at evening, twice a week, until the fruit was nearly full size. The result was double [illegible] on those plants the liquid was applied to, than was obtained from those right alongside where none of the liquid was applied. Let all give it a trial.—*Selected.*

FERNS IN THE NEIGHBOURHOOD OF BOMBAY.

The messman at Khandalla Travellers' Bungalow writes to me, under date of July 19, "that for the last three days there have been very few showers, that the rain when it falls is not heavy, only drizzling. The fog occasionally spreads over the place but does not last each time more than fifteen minutes." He concludes his letter as follows :—"The weather is clear and pleasing for the visitors of Sunday passers." I hope the meaning of this sentence will be clear to your readers : it is rather vague to me. I passed through Lanowlee the other day on my way up the line. I bought a magnificent bunch of growing maiden hair, silver, and hard ferns for four annas. The collectors of these [illegible] should be encouraged. They have to trudge away [illegible] or three miles off, and take their chance of a stray customer. They sell the ferns with plenty of root, so that they are sure to grow when potted.

Though the Khandalla hills are very prolific of ferns, yet the variety is not so great as at Matheran, where one year I collected more than twenty kinds. The most beautiful and rarest of these is the climbing fern, which can only grow as a creeper up the stalk of a friendly sapling. The leaves of this fern are of a most unusual shape, being very much in appearance and size like the human hand. I have only found it in Elphinstone valley in the thick jungle below Hart Point, and even there it is rare and difficult to find. I am told it has been seen growing on Sion Hill near Bombay, and one year I found it growing in profusion in the Tulsi valley near the new masonry dam. This was during an expedition some day made to the Kennery Caves, which are just below the Tulsi valley. This fern grows only on red soil, and thrives well in Bombay. The pot should be suspended in the verandah or hung under a mango tree ; the fern climbs the strings and hangs over in festoons. A strong plant will climb as high as nine feet, and as the leaves keep green all through the year, it is very pretty. If any of your readers feel inclined to prospect for this fern the monsoon is the time, when a visit to Tulsi and Kennery is most enjoyable. In cloudy weather one keeps cool, and the chance of a smart shower adds zest to the expedition. I have found the fern *above* the masonry dam on the south side, and *below* the dam on the north side. The roots can only be got out with an iron tool.—*Cor., Times of India.*

TEA.

The imports of tea to Great Britain in June and in the first half of this year exceeded those of the same periods of last year by 2,435,636lb., and 16,794,067lb. respectively. The figures were 4,728,237lb. against 2,292,601lb., and 54.424,937lb. against 37,630,870lb. A comparison of the deliveries for home consumption shows an increase of 4,872,736lb. for the month, but a decrease of 8,701 832lb. for the six months. In the former case the quantities were 12,226,451lb. against 7,353,715lb., and in the latter 78,224,094lb. against 86,925,926lb. For the month, the exports show a considerable improvement, and were 4,101 960lb. against 2,421,271lb. For the half-year, they were 17,346,200lb. against 17,[illegible]491lb. The stock in the bonded warehouses was 61,332,811lb. against 49,092,387lb.—a surplus of 12,240,424lb. instead of as was predicted in October last by some of the trade a still larger deficit.

The prospect of war between Russia and China has raised the question how such a war would affect the tea industry in India, if indeed it would affect it at all, and we observe a letter on this subject from the London correspondent of a contemporary whose energies are entirely devoted to tea, in which this question is discussed to the exclusion of every other. The writer is apparently either entirely ignorant of, or has quite forgotten, the existence of certain Treaty ports. He takes for granted that the great European Powers will not be able to prevent Russia from blockading the whole sea coast of China if she can, and that there will thus be a chance for Indian tea. We ourselves think there would be a chance for Indian tea if the war broke out, but for a very different reason. We do not think that Russia would do much in the way of blockading, because she is totally unfit to provide a sufficient number of vessels for such an immense sea-board, and because she has no control over the Treaty ports. Hence her efforts at sea would be devoted towards intercepting the arrival of military stores, and such tea as is made in China would find its way out in the usual manner, but we do not anticipate that so large a quantity would be made. The people's attention would be distracted, and trade relations generally dislocated, and industry never prospers simultaneously with war in any country. The customary advances would not be made by the hongs in the several shipping ports, at least they would not be made so freely, and thus the entire industry would suffer. In this way we fancy the tea industry of India would have a chance, and no doubt the various tea companies would be eager to avail themselves of the opportunity. This we are afraid they would not be able to do, because of the present system of manufacture. Any deficiency that might arise in connection with the China tea crop would consist of the finer qualities. These require considerable trouble and cost in production, and the general disorganisation of the interior would tend to everything [illegible] done in a hurried and perfunctory manner. The necessary [illegible] would not be bestowed on the manufacture of [illegible] deficient in quantity, and [illegible] that [illegible] Indian teas are ma[illegible], and are not adapted for [illegible] who is in the habit of continua[illegible] at all hours of the day and night, may r[illegible] we know the majority of planters do, but [illegible] general public, not having been thus educated, [illegible] The tea is made with a view to the development [illegible] rather than delicacy of flavour, and the ordinary [illegible] prefers the latter.

Why do Darjeeling teas sell so well? Simply because they are made with a view to their being drunk pure and unmixed.

When an article is produced in greater quantity than the demand warrants, stocks rise and prices fall, and we naturally look to find that particular variety of the article which offers the smallest intrinsic value to the public suffering the most. This is not the case with Indian tea, which is vastly superior to the China article, even after making allowance for the increased price it realizes in open markets, but the artificial way in which the whole business is conducted leads to the abnormal result of the rubbish being sold and the good article lying in stock. This state of affairs will not be put to rights till Indian teas are sold pure and unmixed, at their fair market value of course, and manufactured with that view. Then we may look for a healthy trade, and something like a return of the palmy days of tea in India.

Complaints still continue to be received of the adulteration of China teas. "Highly faced with Prussian blue and turmeric, foreign leaves present, sand, magnetic oxide of iron, clay, withered leaves, faced nutshells, redbole, and sulphate of lime,"—such, according to the *Melbourne Argus*, are a few of the ingredients contained in China importations intended for Australian stomachs. We hope our friends relish the mixture. But it seems that there is a limit to the colonists' power of endurance, and we are told that so far from the Victorians drinking the above mixture themselves, it is re-exported from Victoria to tea-drinkers with "less money or less discrimination." Who the ultimate consumers of this stuff are we should be curious to know. They must have stomachs like ostriches. And yet the *Melbourne Argus* asserts that tea imported from China is on the whole "well worth drinking, and well worth the money." We are afraid our contemporary gets a little confused when writing on the subject of tea. We pointed out the other day, the strange incoherency of some remarks this paper made on the Australian wants as regards tea. "Indian teas" said the *Argus*, "which have hitherto come to Melbourne, have, as a rule, been dearer by 5*d*.or 6*d*. per lb., than the teas ordinarily consumed here ; cheaper kinds than these will of course be sent, for it seems to be now understood, by the persons interested, that *there is no demand for the high priced kinds in Australia*." A little further on, in the same article, the *Argus* adds :—"*Pekoe Souchongs and Pekoes would be the best varieties to send. The common Souchongs and Congous are too rough to suit the Australian market.*"

Here is another specimen of ignorance taken from the *Daily Bulletin*, a New York commercial organ, from which we should have expected better things. "The Indian teas though lacking the mild flavour of the Chinese plant, have decided merits ; they are one-third stronger, can be sold cheaper, and are unadulterated." Now in the first place we are curious to know what sort of a flavour the *Bulletin* refers to. It must be, we should think, the flavour produced by the Prussian blue, &c., &c., as enumerated above. In the course of the comparison it institutes between the products of the two countries, the *Bulletin* says that Indian tea "*can be sold cheaper.*" If this were so, we should very soon see Indian tea assert its proper place in the markets of the world. But it is not the case, although it is now being sold at prices that are ruinous to the growers. It is generally well-known—indeed it is perhaps the chief obstacle that hinders the largely extended consumption of Indian tea—that we cannot sell as cheaply, quality for quality, as the Chinese can, and principally for the reason that our system of classing is so different. But, for all that, we look hopefully forward to the time when Indian tea will have a fair trial everywhere and be judged on its own merits, which it can very well afford to be. Meanwhile, this very practice of adulteration

of tea in China, will doubtless hasten the time when Indian tea will supplant it. The Heathen Chinee may take the warning, however, which our Government have more than once impressed upon him in connection with this subject. It was not so long ago that 7,000 chests of dust-filings and maloo mixture, miscalled tea, were burnt by order of the English authorities. Such measures as this must, no doubt, have a salutary influence on Chinese tea merchants, and they may, therefore, abandon these malpractices as they see people's eyes opening to their impostures, and the trade in consequence slipping, past them.

It is said that some of the great co-operative stores in London are beginning to practice the sublime mystery of "mixing." A correspondent of a contemporary writes :—"I lately [illegible] them what pretended to [illegible] in the manage- [illegible] difficulty is overcome ; much [illegible] harden on the surface. of [illegible] to work [illegible] once before. [illegible] this, it [illegible] tion in which Indian [illegible] out. [illegible] nouncements one sees in [illegible] Souchong ' 'genuine Assam Peko [illegible] Not that these goods are really on han[illegible] dors, quickly recognising the public de[illegible] endeavour to pass off their celestial atroc[illegible] e."

We give prominence to the following extract from [illegible] Indian teas by Messrs. Gow and Wilson dated London, 3rd August :—

"As there is every prospect of a large increase in the yield of Indian tea, it becomes a matter of serious consideration to all interested that the demand should, in like proportion, increase also. In our opinion there is but one way [illegible] this end is to be obtained, namely, by producing an article which can be consumed pure, and unmixed with its China rival. A gradual but entire change seems to have come over the style of manufacture, of late years, and it is now a difficult matter to [illegible] a tea which bears the "Old fashioned Assam Tea" character. The main object appears to be to convert the leaf as quickly as possible into dry tea, without regard to the fact that in the process of manufacture certain chemical changes must be allowed to take place in the leaf, if the bright ruby liquor and a full and good flavor is to be obtained. We know that in some gardens insufficiently withered leaf has been rolled and fired off in a very short space of time, without any regard to what used to be called "coloring" or "fermentation ;" it is then as expeditiously sorted, refined, and packed, and the result is that a quantity of the tea that comes to the market, though pungent, is thin and uncured. This we may say is scarcely the description of tea that can be drunk pure and unmixed. We do not advocate the manufacture of teas without pungency, but we must have thicker and richer tea than is now sent. More time and pains ought to be bestowed on manufacture, especially, on the withering and final firing, which latter operation used to take eight or even ten hours, but is now performed in about thirty minutes."

Our American cousins appear to be going ahead in the production of tea. The *Home and Colonial News* tells us that four samples of exceedingly well made teas of American growth have been received in Mincing-lane, for examination and report on behalf of the American Department of Agriculture. The teas were made by Mr. Jackson, formerly of Assam, on his estate in Georgia. The Pekoe and Pekoe Souchong are reported on as being remarkably fine in liquor as well as in leaf, and in a good market would command a long price ; while the Souchong and Congu are reported on as being very inferior to the others in liquor, being weak and tasteless. We doubt whether tea manufacture on a large scale could ever pay in America, as labor, in the Southern State especially, is difficult to obtain and very costly.

TEA ADULTERATION.

The Melbourne *Argus* publishes a long article on this subject from which we make the following extract :—

A few weeks ago a discussion was carried on in our columns by means of letters, touching the quality of the tea supplied to Victorian consumers. Letters from correspondents well acquainted with the tea market of the city showed that while there is an extensive manufacture of villainous compounds in China, to be exported as tea, there is at the same time a vast export of really good genuine tea from that country. Also that of the adulterated tea sent out, very little comes here, and when it does come, it does not go into consumption, but is re-exported to countries where the tea drinker has less money or less discrimination. Further, we find that the great bulk of the tea sold here is good, pure, wholesome, and cheap—that if we do not get the best, we get what is good value for the price paid for it, and could only get better by paying a higher price.

As to the comparative merits of Chinese and Indian teas that is not a question easily settled. There are excellent teas produced in both countries, but the Indian teas are dearer, and are new to the palate of English and Australian people, while with good Chinese tea we are well acquainted and have got accustomed to the familiar thing. The pure, strong, pungent; Indian teas appear to be most valuable for mixing with weaker teas so as to enrich and fortify them, and it is most desirable that they should continue to be imported into the colony. But the consumer will not be forced to buy what he does not relish, and of course the importer, the middleman and the grocer, prefer to supply what is in demand instead of exhausting their efforts in a vain attempt to educate the public taste. As a matter of fact, the importation of Indian teas has steadily declined. In 1873-74 it amounted to 77,000 packages, while in 1878-79 it was only 22,000 packages.

In 1877 a series of analyses were conducted in the Technological Museum Laboratory by Mr. J. [illegible], assisted by Mr. Frederic Dunn, to test the quality and genuineness of the tea then sold in Melbourne, and from the recorded results we shall now give a few extracts as a contribution to the tea controversy, premising that the authorities lay it down that :—

"Genuine tea contains between 5 and 7 per cent. of mineral matter, 3 per cent of which consists of soluble salts.

"And that in its ordinary air dried condition pure tea yields an extract equal to 32 per cent., while some choice samples have been found to yield so much as 50 per cent." Accepting this as a standard of quality, we now give a few of the determinations made at the laboratory, beginning with samples of green tea :—

No. 1, classed as "very bad" (2*s*. 6*d*. per lb.), was found to contain, in 100gr., 16·50gr. mineral matter, 23·75gr. extract, 2·00gr. soluble salts, with the following remarks added :—"Highly faced with Prussian blue and turmeric, foreign leaves present ; sand, magnetic oxide of iron, clay, withered leaves, faced nutshells, redbole, and sulphate of lime were found."

No. 2, classed as "bad," 2*s*. 3*d*. per lb. Mineral matter 12·90gr. extract 26·48gr. [illegible] [illegible]·66gr. Highly faced with Prussian blue and turmeric, foreign leaves, sand, clay, and magnetic oxide of iron were found."

No. 3, classed as "inferior" 3*s*. per lb. Mineral matter 13·69gr. ; extract, 30·95gr. ; soluble salts 2·96gr. "Faced with Prussian blue and turmeric ; sand, clay, magnetic oxide of iron, and sulphate of lime found."

No. 4, classed as "good," 2*s*. 9*d*. per lb. Mineral matter, [illegible]·89gr. ; extract, 31·93gr. ; soluble salts, 3·80gr. "Faced with Prussian blue and a large amount of turmeric ; genuine leaves, much broken."

No. 5, classed "very good," 2*s*. per lb. Mineral matter, 6·5gr. ; extract 41·28gr. ; soluble salts, 3·34gr. "No Prussian blue, nor turmeric detected ; leaves genuine."

Now for the black teas.

No. 1, "bad," 2*s*. per lb. Mineral matter, 5·60gr. ; extract, 19·57gr. soluble salts, 2·49gr. "Large quantity of stalks and exhausted leaves ; small particles of Prussian blue and turmeric."

No. 2, "good," 2*s*. 7*d*. per lb. Mineral matter, 3·70gr. ; extract, 305gr. soluble salts, 4·90gr. "Leaves genuine and in fair condition."

No. 3, "very good," 3*s*. 6*d*, per lb. Mineral matter 5·12gr. ; extract, 45·77gr. ; soluble salts, 3·57. "Leaves genuine, no Prussian blue or turmeric."

For comparison with the standard, and with the analysis of Melbourne teas (presumably chiefly Chinese) already given, we add the results of an examination of Indian teas, which has been made by Mr. F. Dunn at the laboratory at our request :—

A—A green tea, about 2*s*. per lb.—Mineral matter. 6·57gr. ; extract 41·23 4gr. ; soluble salts. 3·34gr. "Very good. Free from adulteration of any kind, and from colouring matter."

B—A green tea, about 1*s*. 9*d*. per lb.—Mineral matter 6·25gr. ; extract 41 23gr. ; soluble salts. 2·55gr. "Fair quality; soluble salts rather low ; leaves genuine, but very large. Free from coloring matter ."

C—A black tea, about 3*s*. per lb.—Mineral matter. 5·86gr. ; extract. 32·97gr. ; soluble salts, 2·72gr. "Leaves genuine and of good quality."

The practical value of the laboratory tea analysis, of which we have given a few samples, would be greater if we know to what extent the samples examined were representative of the bulk of the tea imported into the colony. In the absence of the information obtained from them is more curious than useful, for while some of the teas found to be of the highest quality may be largely used in the colony, and the worst only [illegible] very inconsiderable extent ; still the direct contrary may be the [illegible] state of the case. Still the determinations are useful as well as interesting. Of 33 samples of tea examined, 10 were found to yield higher than the standard percentage of extract, *viz.*, 32 per cent , while a few came nearly on to the 50 per cent. only to be found in choice samples. The Indian samples to be seen stand high in this respect, the best containing 41·28 per cent., and the other two respectively 32·16 and 32·97. But several of China teas gave higher per centages, ranging between the standard and 45·7.

It is in their percentage of mineral matters that the Indian teas show best. The standard of genuine tea being between 5 and 7 per cent., the three samples of Indian examined showed respectively 6·57, 6·25 and 5·28 per cent., being as nearly as possible what they should contain to be pure. Some of the Melbourne teas showed very badly in this repect, ranging up to 24 and 27 per cent. of mineral matters. On the other hand some samples had less than 4 and several less than 5 per cent. Where the very large percentage of mineral matters appears, it is due to the presence of sand, clay, magnetic oxide of iron, sulphate of lime, &c. It is to be observed that some of the samples examined at the laboratory in 1877 may have been Indian tea, but there are not likely to have been many of these, seeing how scarce Indian tea was in the Melbourne shops as compared with China tea.

COFFEE.

COFFEE planting in Ceylon is not just now a flourishing industry. The crops of the season 1880-81 will be very short, and a local paper, which has been going into calculations, observes that taking the three main sources of the world's supply together, it looks as though there would be at any rate more coffee in the next twelve months than in the preceding year, and if there be any force left in statistics, we are unwillingly driven to the conclusion that there is but little prospect of better prices [illegible] for the bulk of Ceylon coffee in 1881 than in 1880.

THIS year's Java coffee crop the *Straits Times* tells us is estimated at 731,890 piculs. The spread of leaf disease in Java has led the N. I. Agricultural Society to propose to coffee planters there to subscribe to a fund amounting to 250,000 guilders as a reward to whomsoever shall invent a satisfactory remedy for the disease. The managing committee of the Society acknowledges that there is not much hope of finding this remedy which had been unsuccessfully sought for in Ceylon during the last ten years, but holds that some method of extirpating the fungus hitherto not thought of in Ceylon might be discovered in Java. The Merchants' Association at Samarang has taken steps to call a meeting of coffee planters there to discuss the subject and devise measures to check the disease. The Chief Inspector of Government Cultures in an official report on the coffee leaf disease declares that the latter has long been kn[illegible] in Java, its wider prevalence now being due [illegible] the [illegible] continuance of wet weather. As remedies for the disease he recommends better and deeper cultivation of the soil, especially heavier manuring, to enable the sickly trees to be strong enough to throw off the disease. The Batavia *Handelsblad* calls attention to this plan having been tried and having failed in Ceylon.

LIBERIAN COFFEE.

I.

AS the cultivation of this product nearly resembles that of the coffee of the hills, any remarks as to its culture, &c., may at first strike the reader as superfluous in a country where coffee has been grown so long and so successfully as in Ceylon. But there is as much visionary expectation on the one hand, as there is unreasonable prejudice on the other, for and against it, so that a few remarks, made after a practical study of its cultivation, may be of use in dispelling both. Thanks to Messrs. Cruwell, Agar, and Smyth who ventured on to the unhealthy West Coast, selected and introduced,—in one case at a considerable loss,—Liberian seed in large quantities into Ceylon, there is now no difficulty in procuring seed, each cherry costing not more than one cent., or Rs. 10 per 1,000. There is little to say about the nurseries; provided the seed is fresh, it will germinate readily; be careful to have no drip, plenty of light under the shading, have the beds well dug up, see that the seed is thoroughly soaked, and is sown very shallowly flat side down, and the nursery will be a success. The beds should be kept only damp until the cotoledon is developed; the seedlings should be pricked out into baskets or bamboo pots until they are large enough to plant out, when they should be carefully and cleanly turned out of the basket, or 'split' out of the bamboo, so that the plant with the earth in which it has grown is undisturbed. The holes should be quite twenty inches, and be carefully filled in, ramming down the earth well. As regards the distance which the plants are to be put apart in the field, it will depend partly upon the seed used, and the climate, in our remarks on cacao we said that *with* cacao, Liberian should be planted 15 feet by 15 feet; planted by itself, with the ordinary seed in a non-forcing climate, we think 9 feet by 9 feet the right distance, although with the giant variety, such as *Hooper's crab apple*, we expect 12 feet by 12 feet would not be found too far. Taking 9 feet by 9 feet as the distance apart or 6,000 trees to the acre, the cost of opening one acre will be as under.

Rs. 30	...	...	for	Plants
3	...	...	"	Lining
10				Holing
15				Felling
8				Filling in
8				Planting
Rs. 74	total			

The plant having once started, the growth of the tree is most encouraging: we know of trees ten feet high in two years; and recently saw a considerable acreage of Liberian, topped at five feet, bearing quite seven cwts. an acre and not more than three years old, the clusters growing where they grew last picking,—a distinct peculiarity of this coffee—and numbering from forty to sixty berries each, one large cluster having as many as 110 berries upon it. The best land for Liberian should be flat, or gently undulating, and well drained, the rainfall should be moderate only, and no shade should be allowed. The seed should be taken from as old a tree as practicable, the bean should be short and round, and the skin comparatively thin. Leaf disease, although shewing itself in the mottled appearance of the smaller branches and some times on the stem, has no appreciable bad effect on the vigour of the tree, or apparently on its bearing, and the crop ripens steadily if slowly.

Regarding the "extreme pungency," of the liquid, so commonly talked about, we maintain it is a mistake, the flavour, though a distinct, is an agreeable one, and, after having become accustomed to it, we can quite conceive people preferring it to the ordinary coffee; the oft repeated assertion that it is not fit to drink, is only one of many prejudices that exist against this product, which will however rise superior to all such attacks; there is no reason why every low country hut should not be shadowed by its beautiful foliage, or why it should not usurp the place of thousands of acres of tangled jungle, affording a sure livelihood to the native, if he has only the common industry to plant it; and to the planter, who is willing to brave the monotony and heat of the plains, it offers, as recent prices will shew, every prospect of fortune.—*Ceylon Times*.

II.

PRACTICAL HINTS ON GROWING IT.

THE greatest care should be used in selecting the seed, which should be [illegible] and of long and full-bodied shape, with a thi[illegible] [illegible] half inch ring; fresh [illegible] [illegible] with parchment [illegible] appear for a long time [illegible] is risky), the small seed-[illegible], and when nine inches high, or [illegible] planted in the clearing. The young plants [illegible] to enable them to withstand the first shock o[illegible] ten per centum of failures may be expected [illegible] readily; the holes need not be more than 18 inches [illegible] carefully filled in; planting by turning the plant [illegible] basket with the earth adhering to the roots may be safel[illegible] most [illegible] 8 × 8 feet is sufficiently wide apart for the tree [illegible] which case, at two years, 3 cwt. to 4 cwt. per acre may be expected. The crop will not all ripen, the larger clusters will necessarily diminish as the fruit increases in size by being 'pushed out,' and in dry weather many of the cherries will get dried up and light; about 44,000 beans parchment [illegible] a bushel, and say, fifteen bushels of cherry to 1 cwt. coffee. The fruit takes quite one year to fully ripen. Leaf-disease will invariably attack the nursery, but will gradually lose its ill-effects as the tree grows older; when it also will much better resist the effects of drought; well grown trees should be fully six feet high a two years old.

We imagine the most suitable climate for Liberian coffee is that with a mean temperature of 78° to 80°, and a rainfall of 80 to 100 inches in the year; it adapts itself to almost any soil, but on account of its long tap root, prefers a deep black one; in damp soil, it sometimes suffers from bug. It is one of the most beautiful of trees, and yields both crop and blossom on its generous branches at the same time.—*Ceylon Times*.

COFFEE CULTURE IN JAMAICA.

THE following is an extract from an interesting letter of Mr. D. Morris, late of Peradeniya, to the *Ceylon Observer*.

I have been trying to find out why the Blue Mountain coffee of Jamaica is always so good, and how it is that it obtains such high prices as compared with the fine and highly cultivated coffee of Ceylon. Is the coffee grown here a peculiar variety of *C. arabica*? or is there something in the soil and climate, which promotes the larger formation of the essential oils and secretions in the fragrant bean? Whatever it is, it cannot be in the superior cultivation, the more rational treatment of the crop, or the greater care in the curing. The only cultivation which the estates here receive consists in a rough "hoe-weeding," once or twice a year, with no pruning, except what the hoe does, no system of drainage, no terracing, and, as I mentioned before, no manuring! It is true that on one or two estates, such as Radnor, a higher style of cultivation is being inaugurated, but, as a rule, coffee cultivation in Jamaica cannot compare, at all, with what is being done in Ceylon. I say this without the slightest disparagment to the planters of Jamaica; they have had to pass through so many crisis, and to fight against so many adverse circumstances, that, at last, they have been obliged to submit to the inevitable and especially as regards labour, and manage as best they may. It may seem strange to a Ceylon planter, but all the work of pulping, curing, and preparing the coffee, is done here on the estates by the superintendent or overseer, and when the coffee is sent down to Kingston, it is ready for shipment and immediately put in barrels. The system and the absence of large coffee curing establishments must necessarily increase the cost of curing, &c., but it appears to have been pursued here from time immemorial, and planters appear to like it.

Owing to the large areas nominally included under one estate, the different "coffee fields" are sometimes two or three miles away from the works, lying in "bosoms" of the hills, and only visited for the occasional "hoeing" and picking of crop. Out of a nominal acreage of 1,000 acres, often there are only 160 to 200 acres, and sometimes only about 60 or 80 acres under cultivation. The other parts are in "ruccinate" (jungle) or so steep that owing to "breakaways" and rocks it is impossible to cultivate them. This gives a Jamaica coffee estate a very patchy appearance, and as cinchona has not yet been taken up generally by planters, the uncultivated areas greatly exceed those cultivated. Much more might be done with the suitable coffee lands, if a regular system of nurseries was established, and plants put out with greater care. At present new lands are planted up with "suckers" (or rather seedlings) found under the trees. These are pulled up with little or no care, even when they have 6 or 8 primaries, and after being carried in bundles on heads exposed to the full rays of the sun, are put in holes, and allowed to take their chance without shade or shelter. It is strange to hear such plants called "suckers" but that

is the orthodox term for them here, and it is on such plants that Jamaica planters entirely depend for their supplies and for planting up. I was much puzzled the other day with a remark made me by a planter respecting those said "suckers." I asked why these self-sown plants were called "suckers," when evidently they were nothing of the kind. I suggested "seedlings" as an appropriate term, I was told, "No, no, they are not seedlings: a sucker does not become a seedling till it is crowned." This was still worse, and I had to give it up.

With regard to the absence of nurseries and the planting up of land by weekly sown "seedlings," it seems a pity that so much valuable land and so much time should be lost, when the remedy is so simple. The plants thus put in are often 2 feet high, and with several primaries (i. e crowned, as I found afterwards). Their rootlets are torn and lacerated and the check they thus receive in transplanting, and ... en out from shade and ex... ... late to ... ay mm in the manage- ... resi... is overcome; two or three on the surface.

But still, as the ... to work ... they do, they produce ... it ...

The colour of the bean must depend in some measure on the manner of pulping and drying, but so far as I have noticed, the processes in Jamaica are much the same as in Ceylon, except that possibly, here the cherry is allowed to stand longer before it is pulped.

But to return to the question of high prices—Why does Jamaica coffee command such high prices? This subject, and especially in connection with Mocha coffee, must have occupied the attention of coffee planters, ever since coffee planting began, but so far, it appears not to have received a satisfactory solution. Is it temperature, atmospheric pressure, natural fertility, humidity of soil or air, amount of sunlight and excessive stimulation which produces the perfect elaboration of those subtle principles upon which the aroma and active qualities of coffee depend?

With regard to Mocha and Jamaica coffee, there must evidently be a combination of very favourable conditions for the production of beans possessing such salutary and agreeable qualities; but from the subtlety and delicacy of the law of vegetable assimilation, I fear it is almost impossible so to analyse and trace these conditions as to produce their parallel in other coffee-producing countries.

For Ceylon planters there is, however, one lesson which Jamaica coffee may fitly yield. It is a subject of frequent remark in Ceylon, that there was no leaf disease before artificial manures were used, and many good planters believe that if the use of artificial manures had not actually introduced the destructive fungus, it had at least prepared the plant for its attacks, so that it became an easy prey.

I know that the fact that the disease first appeared in a comparatively new district where artificial manures had not been used, considerably weakens this theory, but there can be no doubt that by forcing a plant artificially you introduce new conditions of life which may ultimately prove disastrous. The soil of Jamaica is naturally much richer and stronger than that of Ceylon, and the underlying rocks, composed as they are, of loose and easily disintegrated materials, replace soil lost by waste, with great rapidity; but if the system of *tillage* now pursued in Ceylon had been in existence there generally, fifty years ago, and the rich surface soil had been preserved by drains and terracing, it is quite certain leaf disease would never have been so fatal to the old estates, and with a careful husbanding and manipulation of the natural soil manuring would have been unnecessary, and the coffee trees would have been more hardy—and less prolific possibly—but better able to fight against the attacks of fungoid and other diseases. As far as I have noticed, there is little disease on any of the cultivated plants of Jamaica. With the exception of the *Cemiostoma coffeellum*, a little leaf miner similar to the *Gracilaria coffeefoliella* (NIETNER) of Ceylon, which cause the silvery tortuous markings and blotches on coffee leaves, Jamaica coffee appears to be very free from disease. Our old friend the black bug is here, but it does not give annoyance except, some times, to badly cultivated and young coffee.

The "Bourbon" sugarcane, which cannot be cultivated in Mauritius, on account of its liability to disease, is here a most productive cane, and similarly with oranges, limes, ginger, and pimento. Jamaica cannot be accused of having forced any of her products by manures, artificial or otherwise, and it may be—but I would not like to commit myself to the conclusion—owing to this, that the plants here are so free from the common maladies of cultivated plants.

Now that the immigration scheme is working so satisfactorily, Jamaica's great want, an adequate labour supply, is becoming less felt. At the Government cinchona plantations creole labour is both abundant and good. By entering into an agreement and paying regular *weekly* wages, we are able to secure a certain number of regular hands: others are taken on only when they are wanted. There are several thousand acres of valuable land on the Blue Mountains admirably adapted for coffee or cinchona, and they only require men of energy and capital to ensure their successful cultivation. I do not desire to appear as an advocate for general emigration to Jamaica, but for young men with some capital and determination, I believe the splendid climate and cheap lands of Jamaica require only to be known to attract numbers who now go farther and fare worse.

In connection with the high prices obtained by Blue Mountain coffee, it would under present circumstances be very interesting to test its value under cultivation in Ceylon. As far as I am able to judge the trees themselves do not differ much in habit, size, character of foliage, or in floral organs, from those cultivated in Ceylon, but the plants here, in consequence of good soil and no disease, are undoubtedly hardier, and must possess a stronger constitution than trees which have been subject for many years to the enfeebling ... of ... disease. I believe the experiment worthy of serious trial on a large scale, and it would give me great pleasure to assist any of your enterprising proprietors, who may be anxious to procure a supply of seed from Jamaica, and plant up some 50 or 100 acres in Ceylon for this purpose. The seed has the merit certainly of being thoroughly sound and good, and if in addition it will keep its superior qualities in Ceylon, it would prove a most valuable acquisition. I know that the small lots of Mocha and Java coffee that have been already tried in Ceylon have been severely attacked by leaf disease, but I have not heard whether the produce has ever been tested, or whether Mocha coffee grown in Ceylon is in any way superior to the plantation coffee. To test the matter thoroughly, it would be necessary to plant up a large area with nothing but the imported coffee, so as to be able to ship an appreciable amount at one time. Plants of Mocha coffee being naturally very delicate, they would consequently be very easily affected by the *Hemileia*; but if, as I believe, the Jamaica Blue Mountain coffee is hardier even than your plantation coffee, while at the same time its produce obtains a much higher price, ... possess special advantages at this juncture. I offer the suggestion as a contribution to the present discussion on coffee cultivation in Ceylon, and in the hope that by the introduction of "new blood" the *Hemileia* may receive a material check in the higher and more recently opened estates.

The experience gained in the case of the vine disease goes to prove that new and hardier varieties of plants have been able to hold their own, and to thrive in spite of the prevalency of such diseases as the ubiquitous *Oidium*, and it is to this that we owe the revival of grape cultivation in Madeira and other places, where after the dreadful attacks of 1848-52, viticulture had been almost exterminated.

CINCHONA.

MR. MURRAY, the publisher, will shortly issue a book by Mr. Clements Markham on a subject he has made peculiarly his own: "A Popular Account of the Introduction of Peruvian Bark into British India and Ceylon," and he will give particulars of the progress and extent of its cultivation.

A HOME paper states that cinchona red bark, grown in Jamaica, realised encouraging prices, being, in some cases, double those fetched by Indian *C. Succirubra*. Ten thousand pounds of dry bark were obtained from 2,490 trees, being at the rate of four pounds per tree. A single harvest realised 17*s.* per tree—a result highly satisfactory.

IT appears that the question of a supply of quinine for India, will not be entirely confined to the alkaloid derived from *Cinchona Calysaya* as we have on our table a very fine sample of sulphate of quinine manufactured at Rungbee by Mr. Gammie, from *Cinchona Succirubra*, which is quite as pure as any we have seen of Howard's. We do not think we are over-sanguine when (judging from present results) we predict that the time is by no means far off when India will be able to produce all the quinine required for the public service of the country, and will thus be quite independent of England.

Now that cinchona cultivation is becoming very general and sites for plantations are being eagerly sought after, it is interesting to note every anomaly connected with the growth of this tree. Mr. Hughes, speaking of Ceylon, lays it down, as a general rule, that stiff and tenacious soils should be avoided for cinchona, which flourishes in the island only in rich, friable, or gravelly soils. Elevation also is reckoned important, both there and on the Nilgiris. Elsewhere, however, cinchona appears to thrive under exactly opposite conditions of soil and altitude. In Jamaica, for instance, where the soil is clayey and stiff, *C. succirubra* has been most successfully cultivated, and the recent exportations of bark have obtained high prices. The elevation of plantations there is 2,000 feet above sea-level, an altitude at which our planters would believe it folly to risk the plant. The prejudicial effects of the stiff and impervious soil of Jamaica are supposed to be counterbalanced by the peculiar geological formation of the subsoil, which consists of a porous lime-stone, full of sink-holes, which convey the surface moisture to subterranean rivers. Thus no hard and fast rule can be followed, and the rejection of a site for some accepted disqualification, either on the score of soil or climate, may prove a mistake.

We are not aware that the present condition of the Dodabetta Cinchona Plantation has attracted the attention of Government; if it has not yet done so, it ought to do so at a very early date. To a private proprietor the state of affairs would be a source of anxiety, if not of alarm. The whole plantation is overrun with that stringy moss which augurs decay, every bough and twig is covered with it, and the lower ones already form dead wood. The upper boughs have a mere tuft of green leaves, towards which decay is fast travelling. The whole estate is thus overrun. Whether the moss has its origin in unsuitability of soil or in exposure, or whether it has been propagated by the remnants of the old forest left, here and there, scattered [illegible] it is not easy to tell. The condition of the plantation has attracted attention, and those who have invested their capital in cinchona, would wish to be informed whether such a state of things can be disregarded, whether it means ruin and loss, sooner or later. The absence of information from Government, scientific or practical, on cinchona culture has been very marked of late. State property of this sort has proved remunerative we know, but beyond this, the public has gathered nothing from official papers worth knowing, and Government has even shown itself not posted in, some of the processes which private owners have learnt and practised.

Cinchona cultivation is now the great rage in Ceylon. The coffee planters, what with leaf disease and other drawbacks, were well nigh driven to despair, when cinchona came as a redeeming angel. But there seems some danger of the new horse being ridden to death. The following extracts from a letter, written by a Ceylon planter to a friend in England, contain some interesting information regarding this cultivation :—"I suppose no cultivation has been so widely taken up and rapidly developed as [illegible] cinchona in Ceylon. It is certainly a most bountiful tree, and has changed the aspect of many declining coffee estates to increasingly valuable properties, and in some cases, notably two, where it has attained too, *regular* growth has brought great wealth to the owners. One local newspaper has given itself almost entirely up to its cultivation, and you commonly hear statistics given, and instances quoted, showing how a hundred acres of four-year old cinchona must be worth £40,000. In fact, the fever is now at its hottest stage. The small leafed variety *Officinalis* I have planted 4,840 to the acre. Say 1,613 trees mature, which at 6 oz. to a tree is equal to about lb. 600 bark, which should be worth say Rs. 900, in four years' time, which means, at an expenditure of Rs. 60, an annual profit of 12 per cent. This is my own estimate. Of course if you are fortunate enough to get fine land with a gravelly subsoil and good natural drainage at an elevation of say 4,000 to 5,000 ft., I know no reason why those enormous profits that have certainly fallen to some, should not also be yours, but it is a venture and in most instances, a terribly disappointing one. To sum up what I have endeavoured to say, I would not advise you with no knowledge of the subject to go into cinchona, but should recommend you to stick to coffee, which to my mind is much safer and generally more remunerative than cinchona, and provided you got into a good district, will give you nearer 20 per cent. than 12 per cent. At the same time I must tell you that the land in which my cinchona is growing is poor, high and exposed, in fact, will grow nothing else, and yet I expect 12 per cent. on the outlay."

A correspondent writes :—"I find no mention made any where of an interesting experiment that has for some time been carried out on Mr. Money's Deva Shola Estate. The bark on a portion of the estate was scraped off the entire stem. Although the dry weather succeeded, the trees thus treated showed no symptoms of injury. The entire removal of the bark from the stem is viewed ordinarily, as an operation so opposed to the accepted theory of vegetable life, that the survival of a tree after it is somewhat of a phenomenon, but in the case under notice, thousands of trees have been so treated without any apparent injury as yet. The foliage of the head is green and fresh, and the bark has renewed with wonderful rapidity. Mr. Barlow, the late Commissioner, spent some time on the estate to ascertain the conditions under which the experiment was being carried out, and the mode of operation. These were duly reported, I believe, to Government, but nothing has yet been made public. Surely there is no more important subject to the cinchona planter than the method of harvesting the bark. Government is apparently unconcerned, but Mr. Money, I should think, might oblige by telling us all about the matter."

THE CINCHONA FORESTS OF SOUTH AMERICA.

At the last meeting of the American Pharmaceutical Association, Mr. Henry S. Wellcome gave a long account of his recent visit to the cinchona regions of the South. Mr. Wellcome expresses much sympathy for the Indian collectors of the bark, describing the climate as deadly, the land as dangerously precipitous and treacherous, and the pay miserably small ; he concludes his remarks by saying that continual wars and revolutions render all investments hazardous, and stagnate all enterprise ; even, when the bark is collected ready for shipment, the roads and ports are often blockaded for months, entailing heavy losses upon the dealers. From his rather copious notes we have extracted the following, he says :—"I shall speak more particularly of the cinchona forests of Ecuador, once the only source of bark and still yielding large quantities. The bark territory, is divided into the districts known as Bosque de (forest of) Guaranda and Bosque de Loja.

The Bosque de Guaranda is a vast forest, extending from about 1° N. to 2° S., and covers the western slopes of Chimborazo and the outlying range of the Cordilleras to more than 10,000 feet above the sealevel. The district is the source of most of the barks exported from Guayaquil, and has never yet been fully explored. Guayaquil, the main shipping port of Ecuador, is a city of 30,000 inhabitants, situated on the Guayaquil River, 60 miles from its mouth. The river is navigable to this point by large ocean steamers.

The elder cinchona district, Bosque de Loja, was the source of the first barks taken to Europe. It extends from 2° S. to 5° S., the boundary line of Peru, and covers the western slope of the Cordilleras. The district has [illegible] constantly for over 200 years, and the quantity of bark it furnishes to the [illegible] market has fallen off during the past few years. Before reaching the highlands, [illegible] quantity [illegible] magnifolia, a valueless species, are met with. [illegible] the desoried some cinchonas in the distance, [illegible] which reflected brightly the vertical rays of the [illegible]

This characteristic reflex [illegible] with the bright roseate flower, affords the best means of di[illegible]ing the cinchonas among the mass of forest giants. The glossy le[illegible] of the India-rubber tree is easily mistaken for the cinchona by a novice but skilled cascarilleros are usually able to distinguish, at a great distance, varieties, by the colour of the flowers and general a[illegible]

[illegible] bottom of the ravine we followed a small stream, till suddenly our guide shouted "cascarilla," and we were gladdened by the sight of several fair-sized trees of cinchona succirubra.

The cinchonas seek the most secluded and inaccessible depth of the forest. They are distributed through in more or less irregular scattered patches, sometimes [illegible] the older trees are really very grand and handsome, 40 to 80 feet high, trunk straight, branches regular, leaves evergreen, 6 to 10 inches long, of a dark green colour, sometimes tinged with crimson, the upper surface of an almost waxy lustre, flowers in terminal panicles of bright rose tint, and diffusing a pleasing fragrance. The bark of the large trees is usually completely covered with mosses of the most delicate lace-like texture, interspersed with the lustrous variegated lichens and diminutive trailing ferns. Vegetable growths develop with wonderful luxuriance beneath the interlacing branches, which permit but the faintest rays of sunlight to filter through them. Everything is saturated and dripping with moisture ; the very air we breathed seemed a clammy vapour. The atmospheric changes are continuous and very abrupt, drifting banks of gloomy clouds are followed by glaring sunshine, and then tempestuous showers, all in rapid succession. The temperature is more even, averaging about 65° F., seldom exceeding 80° F., falling below 45° F. ; altitude about 6,000 feet.

The season for bark gathering begins about August 1 (in some forests as early as June), and lasts till October or November ; during these months the bark cleaves most readily, and on account of the smaller rainfall, the forest is more accessible. It is almost impossible to enter it during the wet season. The trees are first decorticated from the ground up as far as can be reached and then, after felling and removing the clinging vines and mosses, the rough outer bark is beaten off with a club or mallet. The bark is then cut round the trunk in sections of 2 feet to 3 feet, and longitudinally in strips of 6 inches to 8 inches in width, then removed with the blade of a machete. The root-bark is obtained by digging away the earth and cleaving with a machete—a large heavy knife.

When first taken from the tree the inner surface of cinchona bark shows a handsome cream tint (with juice of the same colour), but on exposure to the atmosphere rapidly darkens to a dirty red. The barks are usually taken to the main camp for drying and storage. The thick bark of the trunk requires great care in drying because of the excessive dampness of the atmosphere which sometimes necessitates the use of artificial heat to prevent moulding ; it is piled up in tiers with sticks between the layers to allow free circulation of air, and weights are placed on top to flatten it. The thin bark from the young trees and small limbs dries more readily and rolls itself up into quills.

One of the greatest difficulties connected with the gathering of cinchona bark is that of transporting it to the coast at the end of the season. It is roughly sorted, according to the part of the tree from which it is obtained, and packed in bales of about 150 lbs. each ; the Indians carry these bales on their backs a distance of sometimes several hundred miles to a transfer warehouse, from whence it can be transported by mules to the nearest seaport.*

The final sorting and classifying of barks is done at the main storehouses at the coast† where it is packed in coroons of cow-hide‡, or bales of heavy sacking ; there it is that most of the adulteration and sophistication is done. The admixture of inferior barks with higher grades is not so much the result of ignorance, as has been supposed by many, for the bark dealers are very expert in determining the different varieties and

---

* The worn appearance of most cinchona barks seen in the market, is produced by the rough handling it gets during transportation to the coast.

† In Bolivia the sorting and packing is usually done before transporting to the coast.

‡ The coroon consists of a closely-packed bale sewed up in cow-hide (hair side out). The hide having first been rendered soft and elastic by soaking in water, on drying it shrinks and forms a very strong and firm package.

estimating the values of barks; but, strange to say, very few bark merchants ever become wealthy.

All barks enter the market bearing certain brands, such as "J. P." or "T. B." These brands gain a reputation according to the quality of bark they represent, but it is sometimes the case that, as soon as a brand has established a good name, the dealer sophisticates with the inferior grades§. No large buyers of Europe or America purchase cinchona barks without first making careful essays; but, even with this precaution, they are sometimes deceived, on account of the adroit manner in which the barks are mixed.

As regards the prospects for future supplies of cinchona barks from the native forests of South America the outlook is exceedingly discouraging, the greatly increased use of cinchona alkaloids during the past few years, with the consequent demand for a larger supp[illegible] very thorough working of the ol[illegible] energetic seeking for new ones. [illegible] is overcome; [illegible] becoming more and more rare every year, [illegible] harden on the surface. [illegible] at greater distances from the shipping ports, and [illegible] this, it [illegible]

The tract of country yielding [illegible] s not so unlimited as some writers would lead us to believe, nor [illegible] ly inexhaustible; it is a fact recognised by natives and dealers who [illegible] o well informed about the extent and resources of the cinchona-bearing districts, that if the present ruinous system of destroying the trees is continued, and no effort made to propagate new growths, they will, before [illegible] years, be practically exterminated from their native soil.

With the abundance of seeds yielded by the cinchonas, one would naturally expect young plants to spring up in great numbers, but such is not the case, the light-winged seeds mostly fall [illegible] and adhere to the ever-moist foliage, where they quickly germinate and decay; or if, perchance, they fall to the earth, it is almost impossible to gain a rooting, as the soil is covered to the depth of 10 to 20 inches with loose decaying leaves. Beyond all doubt the cinchonas might be successfully cultivated in their native country, especially in the localities of the exhausted forests, but the natives show no enterprise, and foreigners receive no encouragement from the Government to attempt it. Two Germans have made a venture at cultivating cinchonas near the city of La Paz, Bolivia, but as yet the plants are not sufficiently developed to determine the results.

SERICULTURE.

THE new silk crop in China promises favourable results, and according to the newspapers received from Japan, the crop there also holds out good prospects. The production is expected to be large and of good quality. These facts, coupled with the prospect of a good crop in Europe, tend to show that prices must rule low during the present season.

SILKWORM rearing, to which so much attention and encouragement are now being giving in the Punjab and North-West Provinces, is precisely the sort of industry suited to the Indian *ryot*. No capital is necessary beyond that needed to purchase eggs, &c.; the methods of rearing are simple and easily understood; the food for the caterpillars is never difficult to obtain in this country; there is, and always will be, a demand for the silk, and a fair, if not high, profit may be reasonably expected. The rearing of silkworm may be undertaken by any one without its interfering with his regular occupation. His wife or children can do all that is necessary.

TOBACCO.

EFFORTS have been made, but not with very great success, to cultivate tobacco of superior quality in parts of Arracan in British Burmah. The soil there is said to be as good as the soil in the Phillipine islands, but the Burmese are too conservative to adopt any new-fangled schemes. It is said that if the Government would take the entire scheme in hand, tobacco cultivation might be successfully carried on, and a decided improvement would be apparent in the quality of the leaf.

THE cultivation of tobacco is being vigourously pushed on in parts of Ceylon, and especially in Jaffna where the crop this year has turned out well, and the Colombo market has received large supplies of the leaf. The quantity in store is very large, and we read of shipments being sent to India. The cultivation of tobacco, it has often been pointed out, is one of the most important industries that can be undertaken. In the southern districts of this presidency, particularly in Madura and Trichinopoly, tobacco is extensively grown, and of late years increased attention is given to its cultivation. The cigar manufacturing trade is assuming some proportions, and shipments of cigars are now made steadily to Burmah, the Straits Settlements, and Australia. In connection with the cultivation of tobacco, Dr. Bidie states in the catalogue which he recently published of the specimens sent to the Melbourne Exhibition, that vigorous efforts have been made to effect improvements in the native methods of culture, curing of the leaf, and manufacture of cigars. The Trichinopoly and Dindigul tobaccos are much alike in appearance and quality, but the Lunkah tobacco, grown in the delta of the Godavery, differs materially from both these varieties. As a rule, the Trichinopoly and Dindigul cigars have a stronger taste and flavour than the Lunkah, but the latter although tasting milder, has a more marked effect on the nervous system, and probably contains more nicotine. The exports of tobacco from the Madras Presidency have increase[illegible]; in 1878-79 the exports were 5,223,829lb [illegible] about eleven lakhs of rupees. European firms have started cigar manufactories, and have produced very g[illegible] cigars which are used extensively in the presidency, and efforts have been made to send supplies to foreign countries

§ I was told of one merchant who, thinking his brand sufficiently well-established, made a very large shipment of high-grade bark, with which he mixed about one-third of inferior quality; but the trick was detected in the foreign market, and his entire lot could only be sold as inferior grade, causing a heavy loss and serving him a very just punishment.

TOBACCO.

BELIEVING that many of those who have applied for land in the plains, especially in the Eastern Province, may purpose planting tobacco, and also that the industry will become an important and remunerative one in Ceylon, as it has already become in India, we have prepared the following remarks on this subject, bearing on its cultivation here. From the data in the Madras Government papers on the subject, it appears that the three best varieties to be planted are *N. Macrophylia cor data* heart-shaped Maryland tobacco, which produces a very fine leaf the fine Turkish leaves being probably the produce of it. N. *augustafolia pandurata* stalkless Virginian tobacco, leaves fiddle-shaped, three times as long as broad, this furnishes good leaves for smoking, produces heavily, and is much grown in Germany, *N. Rustica ovata* small-[illegible] tobacco, leaves small, egg-shaped, and smooth, his variety furnishes fine aromatic leaves for smoking, but the yield s low; and *Nicotiana crispa*, furnishing the leaves of the celebrated igars of the Levant, stem very much branched and covered with white hairs, leaves small, stalkless and clasping the stem, flowers red; this species is much cultivated in Central Asia, and we should suspect is a variety that should be introduced in Ceylon.

The tobacco plant has so many species, and sub-species, some being valueless, that we recommend all care to be used in procuring seed. In 1875 the Northern Province alone exported over 35,514 cwts. (returns of which were made) which at Rs. 25 per cent. represent a value of Rs. 1,387,850; the value of the tobacco grown in the Northern Province is not more than 22 cents, per lb. while in India where the cultivation has been well studied, it is worth 44 cents., being just double. The higher class of tobacco (as *N. crispa*) is worth as much more again, however, some Sumatra tobacco having lately sold for the equivalent of 90 cents. a lb. This great difference in price will suffice to shew how much will depend upon the seed procured.

We should imagine that the climate of the Eastern Provinces is most suitable for tobacco, damp weather even during the harvesting is fatal to the leaf, though it is necessary that a certain amount of rain should fall on the plant after being first put out. It is also necessary that the soil be a very light and friable one. A sandy soil containing an average amount of organic matter, well-drained, is the *beau-ideal* of a tobacco soil. Of course the richer a soil is, the thicker and heavier the leaf and the greater the outturn, but this is by no means the object to be attained. The more clay a soil contains, the less will be the aroma, and the coarser the leaf; still even in a clay soil, by proper tillage and digging a good ordinary smoking tobacco can be produced, and if great attention is paid to the selection of the variety, &c., leaf for cigar wrappers even may be produced. Tobacco will not stand any wind, and if planted in new land, so as to avoid it as much as possible, we should strongly advise opening up small plots, well-sheltered, and the result should be a very much larger, percentage of first quality leaf. In a rich alluvial soil little or no manure will be required, but as the tobacco plant draws from the soil the inorganic matter with which it is rich, if the same soil is to be used again, a large quantity of nitrogenous manure must be supplied; as much as twenty-five tons of well rotted cattle manure is applied in Holland, whereas in Sumatra the land once cropped is abandoned as useless. The best manure to produce a quickly burning leaf of fine aroma is potash, which can be supplied by applying 200lbs. of good saltpetre to the acre. We have before said that should the same land be used again it would be necessary in Ceylon to manure it very heavily indeed (this is not the necessity in America, where the soil is rich in plant food, or in Hungary and Holland), but we imagine that inorganic matter such as potash and lime taken out of the soil might be supplied by planting in rotation. Indian hemp is said to thrive particularly well after tobacco, and no doubt Indian corn, Helianthus or any cereal or pulse is well adapted for cultivation in the course of rotation.

We would impress upon the cultivator, that though he may introduce a fine species direct from Sumatra or Manilla, he must be prepared for deterioration; it is unlikely that the new *habitat* will supply the thinness and silkiness of leaf and the aroma, unless, climate, soil, and especially treatment are identical. Now supposing that the object to be attained is a wrapper leaf, then the leaf must be broad, smooth, thin, and elastic, and dried to a golden color, while fine aroma is not indispensable. The variety that most approaches these characteristics is the heart-shaped Maryland tobacco, grown in Germany, and already largely introduced into India. While for a hardy variety the short leafed Maryland tobacco might be introduced, it is a vigorous grower and a good smoking tobacco; but the tobacco that grows commonly and well in tropical countries is the *N. Rustica* growing in Brazil, Turkey, and Asia generally, and furnishing a large leaf, suitable for wrappers, being worth, approximately, 30 cents. a lb. We do not see, however, why with careful cultivation of a small well-sheltered plot, the higher priced tobaccos of Manilla, Cuba, and Havannah should not be cultivated, and made to thrive in the rich soil of the Eastern Province where irrigation is practicable. We purpose devoting a second article to the drying and curing of this product later on.—*Ceylon Times.*

THE INDIAN AGRICULTURIST.

A MONTHLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. V.] CALCUTTA: FRIDAY, 1ST OCTOBER, [No. 26.

NOTICE.

The INDIAN AGRICULTURIST *will be supplied to all Schools and Missionaries in India at half price.*

R. KNIGHT.
Proprietor.

Calcutta, 1st Feb. 1876.

CONTENTS.

NOTICES TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of annonymous letters.

CORRESPONDENCE.

REJECTED COMMUNICATIONS.

E. A. C.—LUNGBA.—Unauthenticated.—We shall keep the manuscripts by us a short time, to give our correspondents the opportunity of complying with our rules, in which case we shall reply to their queries in our next issue.—ED., *I. A.*

WEEDS IN GRAVEL ROADS.

TO THE EDITOR.

SIR,—Can you or any of your readers inform me of any means of keeping down grass and weeds in gravel roads?

GARDENER.

NOTE.—The use of certain strong chemicals has been recommended. We prefer the *koorpee*, as chemicals are apt to destroy any adjoining flower-beds.—ED., *I. A.*

TUSSER SILK.

TO THE EDITOR.

SIR,—Will any of your readers kindly inform me in what district Tusser cocoons are most abundant, and at what price they can be purchased? Any information on this point will greatly oblige.

A SUBSCRIBER.

Ghatal, 6th September 1880.

NOTE.—The Tusser cocoons are plentiful in the Santhal Pergunnahs and Chota Nagpore, as also in the hilly parts of the North-Eastern districts of India. Some information on the subject of Tusser silk will be found in another column. As regards the value of the cocoon we would refer A SUBSCRIBER to the correspondence column in our last number.—ED., *I. A.*

RICE MILLS.

TO THE EDITOR.

SIR,—In the last number of the *Indian Agriculturist*, I see mentioned that new rice mills are being introduced into Rangoon. Rice mills, is what I have been looking out for, for long, but have been very unsuccessful in gaining any information about them.

I shall be very much obliged if you can give me any information regarding these mills, or tell me where I am likely to get such information? What I want is a description of the machinery and working of the mills.

A SUBSCRIBER.

Birdpore, Gorakhpur, 21st September 1880.

NOTE.—We shall see what we can do in this matter, but, meantime, perhaps some of our readers can supply the information wanted.—ED., *I. A.*

CITY REFUSE AS MANURE.

TO THE EDITOR.

SIR,—I have read with much interest an extract from the *Deccan Herald*, in your last issue, on "City Refuse as Manure." To show your readers that this question is receiving attention elsewhere, I would refer them to a report of the conservancy arrangements of the city of Amritsur, which was published in the Supplement to the *Gazette of India* of 19th May 1877. I have reason to believe that the Amritsur system is being gradually introduced into the other Municipalities of the Punjab and probably in other provinces.

PUNJAB.

NOTE.—We shall probably have something to say about the conservancy arrangements of Amritsur, in our next issue.—ED., *I. A.*

VEGETABLE IVORY.

TO THE EDITOR.

SIR,—In reference to the article on vegetable ivory, which you have put in from *Hatters' Gazette*, in your last issue, will you kindly inform your Indian readers where the ivory nut can be procured, if one wishes to plant it. The description given shows that the tree is a palm-kind, very much resembling the cocoanut. I believe it will grow well in the Concan in the Western Presidency, where palms of all sorts grow in luxuriance. If the annual import of the nut into England be of the value of ten lakhs of rupees, then it surely is an article [illegible] cultivating in India.

VINAYAN J. KIRTUNE.

Baroda, [illegible] September 1880.

NOTE.—We are [illegible] aware that the tree has ever been tried, or that seeds are available, in this [illegible] respondent is intent on making the experiment, we would re[illegible] im to apply to Kew Gardens, England.—ED., *I. A.*

THE "SOPARI" NUT.

TO THE EDITOR.

SIR,—Can you tell me—

1. What price "Sopari" or "Goar" nuts fetch per maund, wholesale, in Calcutta, both dry and green?

2. What is the average yield, per hundred trees, of both dry and green nuts?

3. What age the trees are in full bearing, and what age they begin to bear?

4. What soil is most suitable for the "Sopari" tree, what manure, cultivation, &c., is required?

5. And anything in the planting of the trees, preparing the nuts &c. that it is necessary to know?

Any information on the subject will greatly oblige.

SOPARI.

NOTE—1. It is quite out of our way to know the constantly fluctuating market value of produce generally. The information may be had from any broker or bazaar *dalal*.

2. After the tree arrives at maturity, it may be calculated to give about 100 nuts per annum.

3. Begin to bear at 5 years, but are not in full bearing till 7 years old.

4. Almost any soil will do, and it requires little manure or attention of any kind; we may add it thrives best in a tropical climate.

5. There is nothing particular in the planting of the trees, but cattle should be kept from the plants while young. The nuts are prepared for the market by drying in the sun in order to separate the nut from the outer husk—ED., *I. A.*

A SUBSTITUTE FOR THE POPPY.

TO THE EDITOR.

SIR,—I am advised to address you upon the following subject which is claiming attention in this country, *viz*, the necessity or advisability of providing some crops to replace the poppy where it is given up being cultivated, and induce others to replace the poppy by more useful products.

The demand at the present time for material for the manufacture of paper is a growing one on the part of the paper-makers, and the value of the fibre of the "Tree Mallow," for the purpose, has been ascertained and certified to by most of the leading paper-makers here who have offered £10 per ton for it, and who have expressed their readiness to make use of it, could they obtain it in sufficient quantity. Could this plant, which grows easily and luxuriantly in this country, be raised in the vacated fields, in India, so as to form a useful and profitable article of commerce? I enclose a few seeds for trial.

Devonshire, 31st August. A. HAY.

NOTE.—We do not quite understand what our correspondent means by the cultivation of the poppy being given up. We are certainly under the impression it is being pretty largely increased.

The packet of seeds referred to was duly received, and we shall be happy to hand a few to any of our subscribers who care to make the experiment and will report upon it to us.—ED., *I. A.*

VEGETABLE MOULD AND MANURES.

TO THE EDITOR.

SIR,—I feel rather surprised that in a large city like Calcutta, where there are so many plant fanciers and amateur gardeners, some experienced person has not thought proper to attempt the preparation and sale of vegetable mould and special manures on a large scale, as I have not the least doubt of this proving a very profitable business in Calcutta, and a considerable source of comfort and convenience to amateur gardeners. Seedsmen and nursery gardens have recently sprung up by dozens in and about town, and if what I have suggested above is only added to these institutions, the success and anticipations of amateur gardeners, and indeed of our annual horticultural shows, will have been secured, as the want of facilities in procuring manures, the inexperiences of amateurs in preparing them, has been the cause of endless failures generally in raising a fine show of pot herbs and flowering plants.

I wonder that such manures as are adapted to horticulture, &c., are not kept and sold at the Society's garden at Alipore, in conjuction with the sale of plants—where it ought certainly to prove a profitable source of income.

A. C——TTE.

Calcutta, September [illegible]

PAPER FROM MULBERRY BARK.

TO THE EDITOR.

SIR,—Will you permit me through your columns to draw attention to the bark of the black mulberry as yielding a large and valuable stock for paper making.

The mulberries grow extensively and luxuriantly in every part of Bengal, and in fact India, and the one I allude to, the *Morus Mauritiana* (of millid) is no exception to it.

In three years time a tree about 10 to 15 feet high can be grown without any care or trouble, and every inch of the bark can be turned into paper.

Instead of people fighting over the bamboo for a cheap paper stock, could this mulberry not be taken in hand and worked up? A plantation of mulberry requires no care, and the propagation is more simple and certain than that of almost any other sort of plant. My remarks are based on some paper made by me out of the bark of one of these mulberry tree branches. The branch I took was about half-an-inch in diameter, and about four feet long, and out of it I got two sheets of coarse paper about 6″×4″ each in size. I never was in the paper-making business, and my knowledge of it was got out of books; nevertheless I succeeded marvellously well, and I conclude from the ease with which I worked out the stock, and the quickness with which it set, (without the use of starch or any gunny material) that the fibre is a very fine strong one, every way fitted to be worked up into paper of great excellence. Another great advantage possessed by this mulberry bark is that it will require scarcely any bleaching.

I send you a piece of the paper* I made out of the bark in question, for the inspection of those who take an interest in the matter.

J. DENERIA.

* We shall be happy to show the same to any of our correspondents who call.—ED., *I. A.*

TIMBER: INFORMATION WANTED.

TO THE EDITOR.

SIR,—Can any of your readers give me information about a tree which is growing at the lower part of my estate near a swamp? It is a large tree with dark green foliage, and bore a great quantity of seed or fruit this year.

The seeds grow in clusters like a bunch of grapes, and are of a pale yellowish green colour, about the size and shape of a small olive, and each seed pod contains four bright scarlet colored seeds.

A few days before the 'Onam' feast, the Mopahs were very busy collecting the bunches of seeds, and came for this purpose from all parts of Moopenaad. They appear to use the seed for catching birds.

The *modus operandi* is as follows:—A small tree is selected and all the leaves, young shoots, and ends of branches are cut off, leaving only a bare branching stem. The Mopah then provides himself with a quantity of thin bamboo spines about 18 inches long, and coated with a strong gum or bird-lime, and, starting from the end of one of the branches of the tree, commences binding with strips of bark, a row of the seed bunches at intervals of about 9 inches, and so on, until the whole tree is covered. He then takes the gummed bamboo spines, and sticks them in the bark, one over each bunch of seeds, with a slant outward and upwards, and the work is then completed. But although I watched several of the trees narrowly, I never saw how the birds were caught.

From what I could understand from the Mopah's description, the birds settle on the branches and eat some of the seeds, which have a stupefying effect on them, and the birds are held under the lower end of the bamboo spines by the gum, and are taken off by the Mopahs who are watching. These men brought me several parrots and *minas* as presents, which they said had been caught in this manner, but all the birds died within a week after I received them: this may or may not have been the effect of the seeds.

The Mopahs call the tree "Chemboo Maram," which, I suppose, is the Malayalam name, and they say the wood is excellent building-timber. I have been some 17 years in this district, but never saw any bird-snaring done in this way.

I have also lately come across several trees which are excellent building-timber, and do not think they are generally known. One is the

"Navilay Maram," which bears bunches of small blue plums, eaten by Coorumbers and other natives, and the wood is close grained, compact, and hard, durable under water and in damp places, and strong. Another is called the "Carray Maram;" the wood is of a bright reddish yellow, close grained, and easily worked.

Now that gold-mining is likely to increase in Wynaad, timber of all descriptions will become of value, and it is well to know that there is good timber to be had besides the well-known varieties.

F. P. HUGHES, C.E.

Kadalab, Moopenaad, Wynaad, 30th August 1880.

NOTE.—We have not heard of this tree under the name given it by our correspondent, but it seems to be the same that is common on the Kuma hills under the name of Kurruk. The timber is used for the interior work of houses, and the birds feed freely on the berries.—ED., *I. A.*

VILLAGE ARBORESCENT PLANTATIONS.

TO THE EDITOR.

SIR,—For many years, both orally and by pen, I have advocated the partial reboisement of India by means of the village communities, but I do not think that my meaning has been realized by the gods of the Forest Department, as, up to the present time, they do not seem to have made any attempt with the experiment.

There is now a very good chance for such an experiment to be made. Just outside the old civil station at Phillour, a small but valuable fuel plantation is growing up under the fostering care of the Punjab Forest Department. It was commenced about fourteen years ago, and the generality of the trees, where open to the sun and air, are looking very strong and healthy, and are from 6 inches to 12 inches in diameter There is plenty of grass for grazing purposes under the shade of the trees.

My suggestion with regard to this plantation is as follows:—Allow the villagers to graze their cattle and cut wood for home consumption only, and not for sale, in it—of course, under certain regulations not to wilfully destroy any part of the plantation, and only to fell the trees for firewood where marked by the Government Ranger (who should be a European) in charge of the plantation.

Charge a small fee for each axe used in cutting this wood (*for home consumption only*) in the plantation; such fuel only to be removed by licensed coolies, who should have a numbered ticket describing why the permission is granted to them; the ticket to be printed in English on one side and the local language on the other. Also, let the axes be of a certain shape and numbered with large figures, the number of each axe to be entered in a book, and opposite the name and address of the owner.

Of course when large fellings for public sales occur, then the ordinary arrangements for working the trees and removing the wood would ensue, and need not interfere with the—so to say—private fellings of the villagers. In fact the branches from these large fellings would make capital fuel for the villagers.

In exchange for the above-mentioned benefits (because benefits they are when one recollects the distance the villagers now have to go for their wood, and to graze their cattle) let the villagers make over to the Government, an area of waste land now denuded of its trees and grass, equal to double the area of the arborescent tract transferred to them, They have the land at the back of the town, it is now lying waste and useless, and it would be a great advantage for many reasons to have it planted with trees. Let the Government set to work and plant that area with trees, and in about a dozen years' time the villagers would be able to use this new plantation as a grazing ground and for their supply of wood, and then allow the first plantation to have some rest; or they could be used in turn so as to allow each a rest.

When the second plantation had reached its twelfth year, a third plantation could be started, which would most likely carry it out of the Phillour township into some adjoining village; no matter, the benefit from the extension of these arborescent plantations is all the same to all parties concerned.

In this manner the villages of India would gradually obtain a large supply of fuel, and so release their cowdung for agricultural purposes, and thus benefit all parties, and in time a large revenue would be derived from these village plantations, though the initial expenses must be borne by Government.

The present plantation at Phillour requires thinning out to the extent of leaving a distance of 16 times their diameter between the trees, *i.e.*, a tree of one foot in diameter would have none nearer to it than 16 feet, the intervening ones being cut away; one of 6 inches would be 8 feet from its neighbours—in this way light and air would penetrate the plantation and allow the trees to grow up strong, whereas now there are several spots where they are killing each other from overcrowding.

August 27th, 1880.

MANURE FOR TEA-BUSHES.

TO THE EDITOR.

SIR,—May I trespass on your kindness and seek information as regards the application of fowls' dung to tea bushes. I have a large poultry yard of Brahma Dorkings and half breeds which yields me together with the geese and ducks, about half a bushel of manure per day, and I have some 100 cubic feet of dung collected. To make and apply liquid manure, would take more vessels and labor than I could afford, so I have thought to mix a bushel of fowls' dung with say 9 bushels of ordinary earth, open out the roots after the usual method adopted here in applying the ordinary horse and cow dung manures, and giving each bush say ¼ peck of the poultry dung mixture,—would this be too much? Would it be better to top-dress under each bush with a certain quantity just after the rains begin? I suspect it would, and would result in throwing out spe[illegible] th[illegible]es.

A tea *garden* is not a garden but a *field*, that is, we can afford the manure to bring up the plots to garden[illegible], nor the time to prune each bush as it should be pruned, or get a herd of a couple of hundred daily-wage coolies to pluck with due regard to the next flush. Manuring must be done within a given time, or it will interfere with other work. Pruning to a certain extent must be "scamped" so as to get through it by the end of February. And as for plucking, it must be rushed at and overcome, not only to get in the leaf before it begins to harden, but to prevent the bush becoming dormant if left unplucked. I might, manage to top-dress and "lightly hoe in" the poultry yard manure between the August and September big flushes, but I do not know how much to allow per acre. Were I to apply too much and heavy rain follow, little harm would, I opine, accrue from its over-heating properties, but if little rain ensues, damage might follow. Books on manuring are all very well for ornamental shrubberies where due attention can be given to each individual plant, but what I desire to know is, what to do in plantation work, for between these is as great a difference as in "private practice" and a "field-hospital" during an engagement.

Pardon me for trespassing on your time, but help, if you can with your advice.

P. L. L.

Bhawarua, 31st August 1880.

NOTE.—Bird dung is fatal to tea bushes if applied undiluted. It would be useful and highly stimulating if applied say in the proportion of one to twenty of cow-dung, the whole thoroughly mixed, and applied, at the rate of say 8 seers per bush. If mixed with earth, that from the bottom of a tank or *jheel* would be best; it might be mixed 1 to 10, and applied one-and-a-half seers to a bush. The best time for pruning is to commence the moment the sap is done, say one week after all growth is observed to cease, and get through with it as quickly as possible; it should all be out of hand long before the end of February. We prefer pruning to be over by 15th January. Immediately the pruning is over, give the garden a deep and thorough hoeing and apply the manure. Rain would not cause heating with this manure, if applied diluted as we suggest. If our correspondent sees his way to applying this manure every year, we would recommend only two-thirds of the quantities per bush, which we have named.—ED., *I. A.*

COFFEE MANURING.

TO THE EDITOR.

SIR,—In a pamphlet by Mr. Eugene C. Schrottky, entitled 'Tea-planting and Manuring," it is written:—

"It is a grievous mistake to defer the manuring of an estate to "the time when the plants, by disease, blight, and reduced yield "per acre, give evidence that the nourishment in the soil is not "sufficient to keep them in health and vigour. . . . .

. . . .

How dangerous it is for planters to wait till the very last moment, before using manure, we have ample proof by the ruin of many coffee plantations in Ceylon and Southern India. . . . .

. . . . "Borer and leaf disease ruined many a fine "coffee estate, and at one time, it may be said, that the coffee "industry of Ceylon was on the brink of ruin, low prices and diseased "estates being the principal causes of it. However, it recovered, "and it recovered by *a systematic use of manure*."

This pamphlet is stated to be a reprint from the *Indian Agriculturist.*

In the last number of this journal, I find an "extract from an "interesting letter of Mr. D. Morris" which compares coffee in Ceylon with coffee in Jamaica, and greatly to the disadvantage of the former. "For Ceylon planters there is, however, one lesson which "Jamaica coffee may fitly yield. It is a subject of frequent remark "in Ceylon, that there was no leaf disease before artificial manures "were used, and many good planters believe that if the use of "artificial manures had not actually introduced the destructive fungus, "it had at least prepared the plant for its attacks, so that it "became an easy prey. . . . . . . there can be no doubt that "by forcing a plant artificially, you introduce new conditions of life "which may ultimately prove disastrous. The soil of Jamaica is

"naturally much richer and stronger than that of Ceylon, and the "underlying rocks . . . . replace soil lost by waste, with "great rapidity, but if the system of *tillage* now pursued in Ceylon, "had been in existence there generally, fifty years ago, and the "rich surface soil had been preserved by drains and terracing, it is "quite certain leaf disease would never have been so fatal to the old "estates."

Now here be contradictions, and I should like to *know* who is right.

For myself I should vote for Mr. Schrottky as his theory is well reasoned out and seems like science and common-sense. I cannot quite follow Mr. Morris when he says "By forcing a plant artificially, "you introduce new conditions of life,"—so I dare say, you do but it strikes me that Mr. Morris by these words means that by giving a plant manure you artificially *force* it, while to my mind it seems that you *artificially force* a plant when you make repeated and repeated calls upon it, that, in a state purely natural it would not receive; and that by manuring it you artificially *feed* it, a well-fed plant with proper care being able besides to do a good deal more than a plant in a state of nature.

Again, if the Jamaica soil is replaced with "great rapidity," that would put another complexion on the question—a new lease of life indeed! Lastly, will tillage in Ceylon or any where else do away with the practice of artificially feeding plants that you expect a good deal from, or, for that matter, *soils* that you expect a good deal from?

I believe that one Jethro Tull, who lived many a long day ago, found that pulverization pure and simple did not "pay" after a time, and at Lois-Weedon I believe that the Rev. Mr. Smith had to artificially feed the wheat on his *lighter* soils. I think that a letter such as Mr. Morris' should not pass through the portals of an agricultural *rendezvous* without challenge nor be presented to the *habitués* as in this case, entirely without comment.

7th September 1880. F.

P. S.—What is "forcing" a coffee plant? The answer that I think most correct is the act of making it bear berries prematurely. If to *manure* a plant, whether with "artificial" manures or others be to *force* it, and if this word be used in an adverse sense, the *whole question* of manuring is brought into dispute. Liebig and Lawes would alike be liable to the charge of "forcing."

NOTE.—Applying manure judiciously is not "forcing." Giving strong doses of hot artificial manures might be so-called. Mr. Schrottky appears to us to be right, as we regard the so-called coffee leaf disease as one entirely caused by want of nourishment to the plants which we have denuded in every way by pruning, plucking, &c. And although the tea blight manifests itself somewhat differently we imagine it to be caused in exactly the same way. True pulverizing alone will only do good for a time, unless new soil from below is turned up to the pulverizing process. As cultivation is generally pursued, by the ryots, only the top layer is so presented to atmospheric influences.—ED., *I. A.*

UNANIMITY AMONGST TEA-PLANTERS.

TO THE EDITOR.

SIR,—Your issue of the 1st September has been received some days ago, but I have only to-day looked into it, and in doing so, have come across your article headed "Unanimity Amongst Tea-planters."

I happened to be the Chairman at the meeting held in Silchar, to which you refer, and the proceedings of which have seemingly moved you to write the article.

I do not intend to enter fully here into such a lengthy question as the amendment of the Coolie Act, but as it appears to me your strictures on the action of that meeting are wrong and not borne out by facts, and that you are mistaken in some points, both in reference to the proceedings of the meeting and the way in which Act VII. of 1873 should be amended, I will ask your indulgence for space in your valuable paper for this letter.

Instead of, as you say, the meeting being wanting in unanimity, the reverse was the case for out of eleven proposals passed, only on one of these was there any real difference of opinion, and that was in reference to the term of agreement. You imply that nothing was done at the meeting, and of course there may be differences of opinion regarding this. But I am perfectly satisfied that if the Coolie Act were amended in accordance with the eleven proposals which were passed, the tea districts to which the Act applies, would be very generally benefited.

As for the meeting being, as you say, "for the purpose of emphasizing the memorial" of the Home "Indian Tea Districts Association," I must beg to tell you that it was for nothing of the kind. Government asked a certain number of planters to give their opinion as to how they thought Act VII of 1873 could be amended. And had I thought that I was supposed to give my vote in favour of the five years' term of contract, just because that Association said it was right, I should not have attended the meeting at all; for ten times rather would I have the present Act than a new Act altered in the way you seem to advocate, and which includes the five years' term. If the Home Association want their resolutions "emphasized" by tea-planters out here, before passing such resolutions, they surely ought to ascertain first if the planters will do so. If they want us to say "hear, hear" to all they advise they must have their party properly educated!

I emphatically think the extension of the term of agreement to five years would be going backward. Instead of being a reform, it would simply be going in direct opposition to what I believe amendment to be. What is wanted far above all other points is, not an extension of contract, but facilities for opening up the country and allowing a free flow of labour into it. A five years' term would therefore be an obstruction and not a facility. We want to be able to land coolies on our gardens at a fair cost, and that need not be, for Cachar gardens at least, more than from Rs 15 to 20 per adult, whereas we have now to pay four times these sums, and the coolies, instead of getting the benefit, actually lose by the expensive system. If the country were opened up to let labour flow in freely, bonuses would very soon disappear from our monthly statements, which I think are the only items on tea gardens that coolies should not have.

My opinion has always been and it is stronger now, that the Coolie Act is a mistake, and if I had my will I would throw it into the fire and make an end of it at once. This opinion I have sent up to Government, and had I thought they would have entertained such a proposal, I should have brought forward a motion to that effect at the meeting at Silchar. For I think the common law of the land is quite sufficient to protect both coolie and planter, and we would be all better off without the special law.

And further, I beg leave to say, Sir, that you have taken one or two unfortunate instances to support your argument that the Act bears heavy on tea-planters, but I shall merely allude to that one about rice. In the tea districts I believe the law is judiciously administered, and we have no just grounds of complaint against it in its working here, the sanitary conditions the proper care of the sick, and the comfortable housing of the coolies, are conditions which every right thinking man would consider himself bound to carry out without any legal compulsion. And, barring the money paid for getting coolies to re-engage I do not see it possible to give our coolies less for their labour. It is therefore not so much in the sections referring to the tea districts that the law needs amendment but while the law does exist, there should be a maximum limit for rice, though, instead of Rs 3, I think it might very well be made Rs 3 8, which a coolie might be able to pay even in extreme times. No one wants to starve his coolies, and tea or any industry should be able to afford wages to keep a man, his wife, and family in a comfortable state, at the very least, so far as food and clothing are concerned. If a garden cannot do that, much better shut it up, and not allow it to continue dragging a lingering existence with the savings which are justly owing to the coolie. There are few gardens I doubt, if any where the men all over earn an average pay of Rs. 5 per mensem, it is therefore perfectly impossible, if coolies are to be kept in health, that they can pay famine rates for their rice, such as Rs 4 or Rs 5 per maund. Even a single strong healthy man cannot pay this without loss of vigour, for he must then eat less, what then must be the case of a married man with a wife and two or three young children who are unable to earn anything? In Cachar, at least, I know there is no need to charge the coolies famine rates. In my own case all my coolies, without regard to Act VII., re engaged or non-agreement,—all alike,—get rice in the dearest times at Rs 3 per maund, and I do not actually lose by doing this, for in ordinary and cheap times the loss is recouped. My coolies are always eager to take the garden godown rice, in dear or cheap times, and yet we are surrounded by a large village population and extensive rice fields, and there is perfect liberty to the coolie to go and buy his rice anywhere. I buy large quantities of rice at a time, and therefore I get it at a price which enables me to sell it to the coolies at an advance of from four to eight annas per pound, and yet not be charging above bazaar retail rates. And, unless there is a very large local village supply, it is better that the garden should provide rice for the coolies, in any case it would be much better for the newly imported coolies, for when they get their whole wages into their hand they are most likely to go and spend a great proportion of them at once on worthless and injurious bazaar stuff, and there is not sufficient left for their rice and other necessaries.

And now, Sir, in conclusion, I beg to say that I think you should powerfully advocate the free flow of labour into the tea districts from all India, so that they will eventually become rice exporting, instead of rice importing countries, and then the special law and the cruel planter will disappear and tea will bloom and flourish and make our fortunes.

WM. AITCHISON,

Doloo, Cachar, 17th September 1880.

NOTE.—Does our correspondent not see that his letter only adds force to our argument regarding the want of unanimity amongst proprietors of Tea Gardens.—ED., *I. A.*

TEA-MAKING.

(To the Editor of the Ceylon Times.)

SIR,—It is commonly understood that the chief reason for the preference of tea over coffee is the facility with which the former is made as compared with the preparation of a cup of coffee. According to popular idea, we have only to put some tea in the tea-pot, pour the water on it, and there you have the tea ready for use. This is perfectly true as regards the way in which tea is usually made, but it is the fact that to produce a really good cup of tea, attention to a few essential points is absolutely necessary, which said points I believe to be rarely if ever attended to. In the first place the tea-pot should be heated by means of a little scalding water before attempting to make tea in it; in the next place, the greatest care should be taken that the water, is not merely what is popularly termed 'boiling hot,' but it should actually boil at the moment of being used. These points being attended to another and equally important one has to be considered which is, that the water should be allowed to stand on the tea for a very short time, three or four minutes being sufficient to extract all their aroma from the leaves, any longer infusion only serving to extract the tannin from the leaf, thereby imparting to the liquor an unpleasant astringent taste.

I have often heard the complaint made of the very astringent flavor of Ceylon tea: you may rely upon it that this unpleasant taste is mainly caused by the length of time which tea is generally allowed to stand before being used. Of course, to adopt the system I have mentioned, and which is invariably used in China, you will have to make a liberal use of the leaf, but unless this is done it is impossible to obtain a pleasant cup of tea. I suspect that medical men will tell us that the constant use of strongly astringent tea, especially if taken early in the morning is very apt to prove injurious to the digestion, but apart from this question it is far more satisfactory to sip a cup of mild pleasant-favoured tea, than to swallow a liquor in which the true aroma of the leaf is overpowered by the bitter astringency of the tannin principle.

OLD CHINA.

August 26.

PEABERRY COFFEE.

(To the Editor of the Ceylon Times.)

SIR,—I notice in the bi-weekly *Messenger* the following statement in regard to peaberry coffee as noticed by the Melbourne Commissioner. Who is right? the *Messenger* or the "Commissioner"—or is the former only pulling the leg of the latter? "Peaberry coffee is not formed of "two beans coalesced" as the *Observer* says it is, but by the abortion of one bean and the filling of the space usually occupied by two beans by the other one. In the fruit of the kittul palm there are usually two seeds with their flat sides together, but sometimes the two seeds grow together and form a single round one. The same thing happens with tea seeds. In either of these cases it would be correct to say that the round seeds were formed of two ordinary ones coalesced, but in peaberry coffee the abortive bean is always present by the side of the round one."

Who is right? The Commissioner who has been appointed on account of his great experience, or the editor of the little paper.

I should like to submit another question. What is the cause of the formation of what are known as elephant beans? Are they simply abortions and imperfections, or are they also two beans coalesced? Some of them, as regards size, might be, for the matter of that, Cerberus coffee,—three rolled into one!

MOCHA.

September 1.

AFRICAN PALM-NUT SEED.

(To the Editor of the Ceylon Observer.)

SIR,—As there are many people now desirous of trying the cultivation of this palm, it will be just as well to mention that if they meet with disappointment, it will be simply the result of bad seed.

The palm *kernels* and *husked palm nuts* are both exported to Europe: neither of these are fit for seed. The outer covering or husk should not be removed; for the same result will follow as when cocoanuts are deprived of their husk and put out in a nursery—rapid growth and short existence. Intending growers should take care to get the seeds in their *natural* state—that is, with their husks or covering—and in a fresh state: they should not be oily to the touch, for then they are old. Immense sums of money were expended on rubbish called Liberian coffee *seed*. The Colony cannot afford in these times to waste money in buying seeds which are unfit for growing; and besides, the bad results serve as a check instead of an encouragement to those who have the funds and energy and pluck to try new products.

TRUE BLUE.

AVERAGE YIELD OF COCOANUT PALMS.

(To the Editor of the Ceylon Observer.)

SIR,—The Commissioner of the Melbourne Exhibition, in his note on the staple products of the Colony, as published in the *Observer*, has fallen into a slight error on the average yield of cocoanut estates. Only on well-kept estates, where anything like cultivation is carried on, does the average yield per tree per annum reach 40 nuts. Where estates are kept clean and not manured, the average yield per tree ranges between 25 to 30 nuts per annum, and in native holdings the average seldom exceeds 20 nuts per annum. There are some trees in favourable localities which yield 150 or 200 nuts. A tree on the estate of a well-known Ekella planter-proprietor lately bore two bunches, the nuts in each bunch exceeding 150! The natives of the adjoining villages flocked to see these extraordinary bunches of cocoanuts: they would have been sent to the Exhibition, but for being so large and cumbersome, and for all the nuts dropping from the bunch by the time they were landed in Melbourne.—Truly yours,

Colombo, 24th August 1880. B.

[An average of 40 nuts per tree was adduced as a high one. We are well aware that for all cocoanut cultivation in Ceylon 25 to 30 would be nearer the mark.—ED., *C. O.*]

THE GOVERNMENT AND THE COAL TRADE.

(To the Editor of the Englishman.)

SIR,—Are you aware that Government have turned coal merchants? At least the E. I. Railway Company, now a Government concern, not satisfied with the powers they obtained for raising coal for their own purposes, are selling coal in the open market in competition with colliery proprietors and, I may say, importers, while, at the same time, certain facilities formerly granted to the coal trade have been withdrawn or curtailed by the Railway authorities. This looks very much like a device to fetter private enterprise, and to usurp, under the shelter of a Government guarantee, a class of business which does not fall legitimately within the province of Government to undertake.

I am sure the gentlemen in charge of the affairs of the E. I. Railway Company, are, in what they are doing, greatly over-stepping their powers, and I am equally certain that it is only necessary to point out their transgression in order to obtain relief. I do not for a moment wish to insinuate that Government has any knowledge of what is going on, or that, as a Government, it is conniving at it, but its duty is clear, viz., to put an immediate stop to these illegal proceedings.

Calcutta, September 1, 1880. MERCATOR.

CROCODILE OIL.

(To the Editor of the Delhi Gazette.)

SIR,—I see by your columns that the Agri-Horticultural Society wish for information on the above subject. Mr. Purcell who, I believe, is now in Hyderabad, Deccan, may have had means of procuring it, and might be addressed through Mrs. Purcell who is in Mussoorie I hear, but I don't think it is procurable in any large quantity in the N.-W. Provinces, though it is pretty largely manufactured by the Sanif tribe in the Punjab. who eat the crocodile, and the Glasgow firm who are anxious to procure it. I would be happy to assist in procuring it if they will communicate with me, care of your journal, as they think it invaluable in the tanning of leather by some new process, it could also no doubt be manufactured in large quantities in Rajpootana where the crocodiles abound in all tanks. I think a factory could be started for its manufacture in Rajpootana, by having a Central Depôt and offering inducements to the natives to manufacturing it, and purchasing it from them.

PHILO.

WHITE ANTS.

(To the Editor of the Times of India.)

SIR,—Will you or any of your readers be good enough to inform me what are the best means for preserving the roots of flowers and other shrubs from the attacks of white ants? I have nowhere seen these insects in larger numbers than in Guzerat, and unless I succeed in keeping them away from my plants, a whole month's labour in trying to raise a garden here will have been lost.

Ahmedabad, July 28. HORTUS.

ANTIDOTE FOR WHITE ANTS.

(To the Editor of the Indian Daily News.)

SIR,—Permit me a corner in your journal to insert the following recipe for the information of inquirer "Anxious":—

Ol. Petroleum	1 part.
Refined Pitch	3 parts.
Crude Acid, Carbolic	2 parts.

Mix.—Painted on the sides of beams, &c., it will effectually destroy "white ants."

September 18th, 1880. G. B. B.

AGRICULTURAL REFORM.

(To the Editor of the Indian Daily News.)

SIR,—We have social reformers, religious reformers, law reformers, and last though not least, agricultural reformers. In no country of the world so many reformers abound as in India. Of course the land is wide enough to contain so many. But we purpose to deal with the last; the rest have become too hackneyed to form the subjects for discussion.

Mr. Buck, of the North-West Government Farm, has found fault with the Indian farmers, and concludes that the native mode of cultivation is defective for the following reasons:—

1. That the natives do not use the English-made plough, and are accustomed to shallow ploughing.
2. That they are ignorant of manuring.

To remedy the first, he suggests the use of the American plough, which is not unwieldy, and is almost of the same value as the native one. We must thank Mr. Buck for this benevolent suggestion, though we cannot say that deep ploughing would bring in a greater quantity of harvests in a country like Lower Bengal. For though his suggestions are not theoretical, yet the geographical situation of the place of his trial does not satisfy us that the same result would follow were the experiment made elsewhere.

With regard to manuring, he has, perhaps, said too much or too little, and to our simple apprehension, to no purpose. To think that the natives are ignorant of the benefits of manuring, is a mistake as much as or greater than to suppose they have no religion, nor society. But perhaps Mr. Buck is not aware of the condition of land in Lower Bengal, and its principal staples of production.

The land in Bengal may be comprised as high and low, hot and sandy, cold and clayey; and the principal staples of production are paddy tobacco, sugar-canes, and pulses.

Of paddy there are two crops—cold and autumnal. The former, which may be called *palustrine*, is obtained from lands which are considered as most unfertile. Deep ploughing of such lands would hardly be advantageous, as the roots of plants will be beyond the reach of air, while manure will be of very little service. The other crop is reaped from either hot and sandy, or half marshy, lands, and for reasons above, it does not admit of deep ploughing, while manure would be only productive of larger stalks with less of corn.

Of the rest of the staples, tobacco and sugar-cane are the productions of high lands, and of naturally rich soil, and if any descriptions of land require manuring and deep ploughing, it is these. But they bear a proportion, it may be said, of about 10 per cent. to the arable land. And although the native mode of ploughing may be defective, yet it cannot be said that they are ignorant of the sort of manure which these lands require.

The manures which the natives use for these lands are marl and cow-dung, and these are found by experience to be the *only* manures which hot and sandy lands require, if the other manures, such as bones, &c., have never been tried.

The only defect, which may be found in Indian agriculture, is the want of a barometer to guide the farmer as to the best season for sowing and mowing.

If our Government take this subject into consideration and supply the Indian farmers with this instrument, we shall feel very thankful. Of course, we mean that every village headman or *mondol* be furnished with it, together with instructions for its use in the vernacular—Yours, &c.,

Sheebarnapur, August 11th, 1880. K.

SERICULTURE IN THE DUN.

(To the Editor of the Pioneer.)

SIR,—I have had sent to me a copy of a portion of your issue of the 18th June, in which there is a very interesting article, by a correspondent, on silk cultivation in the Dun, and which is concluded from the *Pioneer* of the 27th of May. Before I go further, will you kindly permit me to refer to the old adage, that "a fool and his money are soon parted" and after that also to observe that in this sublunary sphere there are people born to waste money, and such people readily find, if they only talk loud enough and print sufficiently, other people and Government officials too, who believe in them, and accept them, as workers of wonders and miracles. A case in point is this monomania for rearing silk worms in the Dun. A man has come out all the way from England at great cost, with a large store of money at his command to cultivate silk in the Dun. He is working with a zeal and energy worthy of a Goliath, he is spending money by the "shovel full," the officials of the Dun are giving him extraordinary assistance, and he believes he is on the right way to a silken "Bonanza," instead of which, from the man's own figures, I predict a general collapse of his business, loss of money, and a grand failure to be placed on record. I leave out all the pretty scenes and romance of your correspondent's letter, beginning with his fine waler and the trap in which he drove down; I leave the French statistics too, and I start on the para. in which Mr. Lepper states that an acre of mulberry will yield 12 maunds of green cocoons, fetching Rs. 30 per maund or "Rs. 360 per acre!" Wha! Wha! how fine! What a fortune! Hurrah for Mr. Lepper! Now, I am a business-man, who can claim about 22 years' experience of raw silk, both tusser and the one being dealt with by Mr. Lepper; and I believe the waler horse, trap, and 1,300,000 mulberry plants will all have to turn insolvent at the rate at which Mr. Lepper purposes to work. Dealing with the 12 maunds of best cocoons, we shall have at most from them 36 seer of best silk, and consequently the silk will stand us Rs. 10 per seers for cocoons only. Say the reeling off of the silk, the establishment, the fuel, &c., costs Rs. 4 per seer—and it will not cost less, unless large quantities are manufactured; add to it transit and packing charges, agency charges, exchange, insurance, &c.; and the sum total for each seer of Dun silk delivered in the Europe markets will not stand under Rs. 16 to 18 per seer. The best surdahs in ordinary season seldom fetch over 30*s*. per lb., and generally sell at 24*s*. to 26*s*, per lb. Now, will you kindly take 26*s*. from Rs. 16, and let me know what Mr. Lepper is going to earn? It is simply absurd to attempt to grow mulberry and rear cocoons, when, in Bengal, about 200 square miles of country grow mulberry and rear cocoons, and the manufacturers cannot make it pay. I have simply dealt with the weight of cocoons and their yield. Mr. Lepper has probably yet to learn that cocoons which spin in cloudy and "muggy" weather yield very bad silk, still worse produce, and a host of other things. The *Bombyx chori* is doomed as the silk of the future. Cheapness is the all-absorbing question of the present end of the century, and cheapness cannot be procured out of the Bombyoidæ—they are the aristocratic cocoons and cost heavily. They are delicate gentlemen, and the least thing lessens their goodness. They must be worked off without delay, and therefore unsuitable to Indian manufacturers. The silk of the future is the tusser. The *anthœria paphia* and its congeners—coarse plebeians who feed out in the open air on the terminalias,—do not care for wind or rain, can be kept a year or two years, and reeled off into silk that could be laid down in Europe at 16*s*. a lb. or even less; all expenses paid. Let Mr. Lepper drop all his Bombyces and take to tusser. He will find tens of millions of *asan* trees—terminalia—wherever the laterite soil exists on which to feed worms; his maund cocoons will cost about Rs. 30, but the yield from them will, on an average, be about 12 seers of silk, which, at the moderate figure of Rs. 10 per seer, will yield Rs. 120, leaving a balance of Rs. 60, at least, after paying all charges. Let him set about this, and the fortune of his principals is secure.

"THE PUNDIT."

The Indian Agriculturist.

CALCUTTA, OCTOBER 1, 1880.

IRRIGATION IN THE PUNJAB.

WE have reviewed the results of irrigation in the widely dissimilar provinces of Bengal and Sindh. The report on irrigation in the Punjab for the past year relates to a province occupying, as it were, a position midway between these two. In some parts of the Punjab, canals are as much a necessity as in Sindh; in other districts, they are more or less a luxury. The Punjab canal system is divisible into four branches,—the Western Jumna canal, watering the districts of Umballa, Karnal, Rohtak, Hissar, and Delhi; the Bari Doab canal, which protects Lahore, Gurdaspur, and Amritsar; the Sutlej canals, extending to Lahore, Montgomery, and Multan; and the inundation canals of Shahpur and the Derajat. Taking all four together, the capital sunk in canals is about 4½ millions sterling, but only 2¼ millions of this represent the outlay on canals actually in operation. It is upon this latter sum, of course, that calculations of profit or loss must be made; and in this respect it appears that the net return, after deducting working expenses, comes to nearly 3 per cent.; while if the land revenue dependent on canals be reckoned in, the return rises as high as seven per

cent. By the first method of calculation, canals would seem to be a losing speculation, for the capital sunk in them has been borrowed at 4 and 4½ per cent.; but by the second method not only is this interest paid off, but a clear profit of nearly 3 per cent. remains over and above. It therefore becomes a question of some nicety, how far the inclusion of land revenue returns is legitimate. Hitherto, in the case of most canals, the estimates have been more or less vague and approximate; a certain share of the assessments has been assumed as dependent on irrigation, but it has never appeared in the shape of a water-cess, nor has it been directly and demonstrably connected with the benefits of canal water. Several years have elapsed since the first attempt was made to separate the water-revenue from the land-revenue in the districts of the Amritsar division. The principle found favour in 1865, when the settlement of those districts was under revision, but it turned out rather badly in its practical development. Briefly explained, the procedure adopted was to rate the dry soil at a low all-round valuation of eight to twelve annas the acre, and then to add special rates for irrigated lands. Canal-watered lands would thus be assessed, for instance, at ten annas per acre "on their dry aspect," as the phrase went, and at twelve annas per acre on their irrigated aspect; total, one rupee six annas per acre. Lands watered from wells were differently treated. To the all-round dry rate was added a rate on wells, distributed over the area watered; thus a well would be rated at Rs. 20 and a village containing (say) three such wells would pay eight annas per acre on the dry aspect of its cultivated lands, and Rs. 60 for the three wells. This method of well-assessment involved a considerable sacrifice of revenue, and has since been condemned. But the method of canal assessment has proved a success, and in the revision of assessment now going on throughout the Punjab, this method has been or will be adopted. This will introduce accuracy into the accounts of the Canal Department, by enabling them to shew, on grounds capable of proof, how much of the land revenue of the province is due to canals. Meanwhile the actual estimate may be accepted as approximately correct, and we can safely assume that the Punjab canals are more than paying their way.

The oldest canal is that of the Western Jumna. It shews a clear profit of no less than 13¼ per cent., *exclusive* of the land-revenue returns. If the latter be added, the profit rises to more than 15 per cent. No doubt the land-revenue due to the canal is at present inadequately represented, and one result of the new arrangements now in progress will be to enhance the profitable appearance of the canal. These favourable results, however, are largely due to the comparatively small outlay of capital upon this canal. A part of the work was done in the days of Moghul rule; the name of Ali Mardan Khan is inseparably connected with it, and the boon conferred by him upon Delhi is still commemorated in the songs of Hindoo women, praising Delhi as a pleasant city, with its water raising gold—*Dilli shahr suhágan, kanchan barsat nir.* Thus the Jumna canal is hardly a fair example of remunerativeness; though, on the other hand, it is to be noted that the year was not a propitious one for profits, the area of irrigation having been materially diminished by the fever which prostrated the agricultural population. The returns for the Bari Doab canal are not nearly so encouraging: indeed, the canal is apparently worked at a loss, for the profits, including land-revenue, amount to little more than 3 per cent. on capital outlay, thus leaving a dead charge of one per cent. for interest. But the loss is only in appearance, and can easily be explained. The assessment of land and water separately, first tried about 1865, did not escape the errors incidental to first attempts. It has already been shewn that the well-rate proved a failure; and the separate rates for canal irrigation, though highly successful in principle, were pitched much lower than those realised in subsequent assessments elsewhere. It is calculated that at the rates commonly prevailing in other districts, the land-revenue dependent on the Bari Doab canal is really sufficient to raise the profits nearly a lakh and a quarter in excess of interest charges; in other words, the canal really pays its way. The settlement in some of these Doab districts is about to come under revision, and we may expect, among other results, a large addition to the amount of land-revenue credited to the canal. In some respects the Bari Doab canal is an exceptional work. It furnishes the first instance of a regularly built weir across the boulder bed of a river in Northern India. The fall is no less than 32 feet per mile, and the rapid volume of water rolls along a broad shallow channel, covered with boulders of all sizes. No other stone is procurable, and the weir had to be built of boulders set in mortar. The escape channel has twice been severely damaged, and probably the work will prove a constant source of anxiety and expense. With every freshet, the river reasserts its tendency to turn bodily into the escape channel, and strike out a new course, quitting its old bed, which has been defiled by the boulder-built weir.

The remaining classes of canals, *viz.*, those of the Sutlej and those of the Indus, are inundation canals, filled only during the annual floods of the rivers from which they are drawn. The Sutlej canals shew an enormous profit, for the simple reason, that the land-revenue is almost wholly dependent upon them. In the Indus districts, the canals have to contend with over-bearing floods, and uncontrollable hill torrents, both of which annually contrive to work much damage, and, as a financial speculation, these canals do not appear to be remunerative. But the truth is, that the canal accounts do not and cannot include all the profit derived by the country from the works. The value of the crops raised on canal-irrigated lands in the Punjab is estimated to exceed five millions sterling; and if only half of this be assumed as creditable to water, such an addition to the wealth and resources of the country would justify even a much larger expenditure than the capital actually invested. Calculations of return on capital may be to a certain extent delusive; they certainly are delusive in the case of the Western Jumna canal, which redeems the whole of the Punjab canals as a financial speculation. But there can be no mistake about the increased productiveness and the protection against famine which are the results of canal irrigation. In the Punjab, at least, these vast public works are amply justified by the benefits they have secured; and it is not unreasonable to hope that the sphere of their usefulness will go on extending year by year.

PERSIAN OPIUM IN CHINA.

SOME papers lately received from the Press Commissioner contain interesting information regarding the extent and development of the trade in Persian opium in China. From the statistics that are given, it would appear that though Persian opium has long been known in some districts, it has been imported only in trifling quantities until within the last two or three years. In 1878 in the consular district of Chinkiang alone, the import of Persian opium suddenly increased to twenty times what it had been before. The following year showed a still further increase in the imports, which amounted to 721 piculs (1 picul being equal to 133⅓lbs. avoirdupois). This increase seems to have taken place at the expense of the Malwa drug; for while both Benares and Patna opium show a very satisfactory increase, the imports of Malwa have steadily declined since 1876 in this district. It is, therefore, evident that Persian opium is not taking the place of Patna or Benares. But there can be little doubt that the Malwa manufacture is better than any of the others. The great rise, however, that has taken place within the last two years in the price of Malwa, has militated against its extended consumption, and in fact so long as Malwa maintains its present high price, there must continue to be a demand for Persian opium. The Chinese do not seem to really like the Persian opium, and only use it for mixing with other kinds (Malwa chiefly), thereby effecting a saving in price.

Mr. Giles, Acting Consul at Amoy, tells us that the Chinese in that part of the empire are decidedly averse to the Persian drug. They say it leaves a rank, frouzy taste in the mouth of the smoker, and causes hot risings in the throat. It consequently finds little favour with the people, unless perhaps when the price of other kinds may happen to be exceptionally high, in which case a mixture of Persian and Indian opium can be procured at a lower rate. Mr. Bulloch, Acting Consul at Chinkiang, is of opinion that the demand for Persian opium will depend on two things: *first*, and chiefly, on the manufacturer's bestowing sufficient care on its preparation; *secondly*, on Malwa's retaining its present high price. As the best Persian

opium, Mr. Bulloch adds, can be mixed with Malwa in equal proportions, it is possible that it may interfere with the demand for the latter to a very serious extent. But it seems that there is no possibility of its ever taking the place of Malwa for separate smoking, unless the Chinese get used to the burning taste in it of which they complain. Such a thing of course is not impossible, but there are no signs whatever of it at the present moment. Chinkiang is by no means the only district where the consumption of Persian opium has suddenly exhibited so great proportions. A glance at a comparative table of the Trade Returns of Kiukiang shews an enormous rise, within the last two years, in the imports of Persian opium. Although the drug has been known in this market since 1865, it has never attracted any notice to speak of, until two years ago, in 1878, when a sudden and unexpected demand arose for it. Mr. Scott, Acting Consul in this district, says the only explanation he can obtain of this abrupt increase in the consumption of Persian opium is, that it was not until 1878 that even the poorest class of opium-smokers would knowingly tolerate any adulteration of the Malwa opium used by them. But in that year they found that the loss of strength and flavour resulting to the latter drug, from an admixture of the former, was sufficiently compensated for, in their reduced circumstances, by the reduction in the price. The debased taste thus forced upon them in their poverty has continued; but it is possible that returning prosperity may again cause them to revert to their former demand for pure Malwa opium. Mr. Scott is of opinion, however, that the ratio of increase in the use of Persian opium for the last two years, will not be maintained; on the contrary, he believes that a decrease will take place. In fact, Mr. Scott attributes the consumption of Persian opium in his district entirely to its cheapness as compared with the Indian drug. The proportion of Persian opium to Malwa, when the two are used together, is, we are told, about one or one and-a-half parts to five. In Kinkiang the well-to-do still smoke nothing but pure Malwa, the other kinds of Indian opium being practically unknown in that market. From what Mr. Scott says, we should think Persian opium will soon find a formidable rival in the native manufactured drug. The former "appears to possess no recommendation other than its cheapness; in strength and flavour it is declared to be greatly inferior to the Indian drug, and it would seem that it owes its prominence in this market, as compared with native opium, to accident; for if it is true that Persian and native opium are, as is asserted, on a par as regards quality and flavour, the latter drug, being only 7-11ths of the price of the former, must, if they come into competition, have the advantage."

Much of the Persian opium that is shipped from Bushire comes from Yezd. Mr. Bulloch tells us it is sent to Hong-Kong on commission, nearly a moiety being consigned to Messrs. D. Sassoon, Sons & Co. The Sassoon firms say that chest for chest their dealings in Persian opium pay them better than those in Indian opium, the loss of interest on the capital inverted in the latter being so heavy. With Persian opium, on the other hand, there is no risk; advances are remitted on its arrival at Hong-Kong, but account sales are, of course, only rendered on the chests finding purchasers. This is doubtless a consideration that must tell in favour of Persian opium. But, notwithstanding that Malwa is thus somewhat heavily handicapped, we have little fear that it will be able to hold its own against the Persian product, unless the latter is susceptible of very great improvement both in its growth and manufacture, while at the same time its comparatively low price is retained.

THE NAGPORE MODEL FARM.

We have been favoured with a copy of the Report on the Nagpore Model Farm for the half-year ending 31st May last. This Report is, as it were, a continuation of, and a supplement to, the Report for the previous half-year. It records the subsequent history of the various crops of which details were given when they were in the ground, at the time the former Report was issued, and in short it sums up generally the results of the year's work. The first thing to which our attention is drawn is, that no rainfall was registered during the whole period of the six months now more particularly under review, whereas in the former Report it was shown that the monsoon rains had been heavier than usual, and that their ill-distribution had tended to increase their bad effect on certain crops and soils The Report deals separately with each of the following crop. —*viz.*, jowari, cotton, thur, linseed, wheat, gram, lucerne, guinea grass, castor, ginger, turmeric, and onions—some of which we shall briefly notice.

Jowari.—The difficulties consequent upon the heavy rainfals of last year prevented a successful crop on any but the best drained soils. Although, owing to the rich nature of the soil around Nagpore, the season was not on the whole unfavourable to the growth of jowari, yet in deep, well cultivated lands, the excessive wet caused these usually favourable conditions to be a source of injury to the crops. But notwithstanding the difficulties encountered with jowari in the past season, it is satisfactory to find an outturn recorded of 300lbs. to the acre over an area of eight acres, some of which is covered with little or no soil; while at the same time, as Mr. Hooper (the Superintendent) tells us, "the compensating high price of *karbi* fodder enabled us to show some return for the labour expended on the crop." For it appears that, unlike that of the grain, the price of the fodder is determined locally, from which Mr. Hooper seems to think that jowari, in ordinary years, is, commercially speaking, as much, if not more, of a fodder than a cereal crop. During the present season, we are told, "the cultivation of jowari will be carried out with the same special objects as during the past year, *viz.*, to determine the relative expediency of thin and thick sowing, and the effect of thorough cultivation of the soil, by ploughing and other means, previous to putting in the seed."

Cotton.—The expectations previously formed as to the outturn, were not realised. The unfavourable state of the weather,—cold and cloudy—towards the end of last year, seems to have done serious injury to the crop, and it was not until three months later when, in the middle of February, a sudden rise in the temperature took place, that the plants revived. Fresh heads then began to appear, which developed into bolls of fairly good cotton, and these "we continued to pick until the month of May." Mr. Hooper is not at all sure, however, that the weather was altogether to blame for the crop. He says, "it was discovered that the small fruit was on too weak a peduncle which dropped from its base along with the young boll and the bracts." Then again, the land on which the crop was grown was heavily manured with poudrette, which Mr. Hooper suggests might be a reason for the abnormal development of leaf, at the expense of flower and fruit, which took place. But against this must be put the fact that on an unmanured field the same cessation of fruiting was observed. On the average about 33lbs. of clean cotton, valued at from Rs. 8½ to 9, was the outturn per acre, but this calculation does not take into consideration the space occupied by several rows of wide spreading thur bushes, which were planted alongside of the cotton, the reasons of which we shall give further on. Though the season was unfavourable, commercially speaking, yet we are told it "was profitable in so far that it gave an opportunity of studying the various effects upon the Hinganghat cotton plants of sudden changes of temperature." This is going rather far in search of an excuse for minimising an evil. We must say there seems to us to be a touch of the comic about this pretended "profitable" result.

Thur.—Some interesting and important information is given under this head. Like jowari, thur suffered from the constant rain and cloudy weather. Insects also, and root fungus which attacked the plant, operated against the crop. It is, therefore, not surprising that the yield was not heavy. Some experiments were conducted in which a mixed growth of jowari and cotton was attempted; and the results obtained were very successful, the return in grain from the bushes grown among the cotton being highly satisfactory. Thur bushes were planted in every fourteenth line, in lieu of cotton, over the whole field of 25 acres. Although this would represent a space of only one-fourteenth of 25 acres, yet, owing to their spreading, the thur bushes actually

covered a much larger area. But, allowing even that the bushes occupied one-fifth (5 acres) of the whole field, the result shows an outturn of 3,600lbs. of grain, or over 700lbs. to the acre. This, we are told, is a yield "more than double what we have registered for our pure thur crops." It should be remembered, however, that the land was well cultivated and manured. Another important result that this experiment of mixed growth brought under notice was the comparatively small damage done by insects to the crop. This was very marked, and Mr. Hooper attributes it "simply to the difficulty the insects had to circulate, except on the line they started from, owing to the cotton plants." But in attempting experiments of this kind it is highly desirable that plants requiring different elements for their support and seeking their food at different depths should be grown together. Of course it will easily be seen that it would not be profitable to select indiscriminately any two plants for a mixed crop. In the case of different grains that ripen at the same time, the difficulty in separating the two (unless the crop had been most carefully harvested), would, at the time of sale, cause serious depreciation in the value of each. For this reason cotton is peculiarly adapted for growing with almost any other crop. The experiment of interspersing it with thur was, as we have shown, quite successful, the only drawback, perhaps, being that both are widespreading bushes. But even this would not be the case, we learn from Mr. Hooper, with a *kharif* grain crop, such as jowari, which "would grow without at all interfering with the cotton, which in turn would not affect it." Attention is promised to this subject in current operations.

Linseed.—Of all the crops on the farm the season was on the whole most favorable to linseed. In fact for this crop the season was almost a perfect one. Much of the large area under linseed was but poor soil, and the average outturn is therefore not considered a "very low one." As far as we can gather, it was 300lbs. to the acre over a field of 6 acres treated in the ordinary way, while over a small area subjected to careful and deep cultivation, and where the seed had been well selected, the average outturn was 624lbs. to the acre—an enormous difference. In some fields—one particularly—the outturn was very poor; the cause assigned for this is the liming given to the soil in 1877 before taking off a crop of sugarcane which was followed by wheat. It seems that the only variety cultivated was the "Gaurani" or "Nagpore," which "contains a large admixture of white among the dark grains, and is on this account richer in oil than the pure dark red variety which is grown extensively in the eastern districts." The whole crop was sent to the Central Jail to feed the oil mills, and it was declared to be superior to any previous lot, "the percentage of oil being higher in direct proportion with the quantity of white seed in the mixture." The pure white seed is undoubtedly the more valuable, and sufficient has been collected to sow a large area with, during this present season. The results of some chemical experiments and analyses are given, but these we need not go into, as they reveal nothing new.

Wheat.—The crop of wheat was on the whole a success. In some fields the average outturn was low, owing to the poverty of the soil, but in others again it was very good. It seems, however, that some sowings were unavoidably late. Could the seed have been put in earlier, the outturn would have been much larger than is recorded. The quality of the Haura and Pissi, *i.e.*, the hard and soft white varieties, was equally good, and the outturn of each almost identical. The demand in the local market runs chiefly on the hard grain, which in consequence commands a better price than the soft white kinds. Irrigation and good preparation of the soil exerted a marked influence over the production of some of the fields. But the good outturn of wheat is attributed chiefly to the manure given. Poudrette, we learn, was largely used, as well as liquid manure. The system of drilling poudrette into the soil (in lines 6 inches apart, on this occasion) before putting in the seed, and afterwards, at the time of the plants coming into ear, the application of a fresh liquid manuring, seems to have had very favourable results, and is specially well calculated to afford immediate results. This system might often with advantage be adopted in garden farming, we should think, wherever water is available.

EDITORIAL NOTES.

During the latter half of September, the fall of rain throughout India has been sufficient to dispel the fears which were entertained as to the prospects of the crops in some of the districts which had not received the average rainfall. This was particularly the case in the Deccan, where a deficient rainfall is rapidly followed by scarcity or famine. An official paper has been published on the condition of the crops throughout the Bombay Presidency. No fears are now entertained of scarcity in any part of the presidency, and, regarding the Deccan, we are told that "in Sholapur the rainfall has been abundant everywhere, and the outlook is most promising. The *kharif* crops have recovered, *rabi* sowings have commenced, and the Collector reports that no relief works are anywhere required. From all parts of the Satara district the latest advices are hopeful and re-assuring. Rain has fallen steadily throughout that collectorate, and the crops are everywhere reviving. A *kharif* crop, averaging eleven annas, is now anticipated. Prices have not risen, and are easy as compared with those obtaining last year. The condition of the people is stated to be good, and they are said never to have lost hope. Any special relief-works are unneeded, as the ordinary local fund works will provide sufficient occupation for any persons who may seek labour."

Agricultural prospects over the country generally are more re-assuring. Until quite recently great fears were entertained of a scarcity on the western side of India, especially in the Deccan. But the latest news from those parts is calculated to allay anxiety, and the Bombay papers assure us that nothing short of some extraordinary caprice on the part of the weather during the present month can prevent the coming agricultural season on that side of India from being an excellent one. The very heavy rain of the past fortnight has removed all ground for apprehension in the Concan, where the rice may be expected to turn out a full average crop. In the Southern Mahratta Country, where anxiety was for some time entertained, there has been a general, a plentiful, and a thoroughly beneficial fall, and even from the hardly-tried districts of the Deccan we hear now that the *kharif* generally has been saved and the prospects for the *rabi* are good. In Sindh, too, there has been heavy rain and the river is rising.

The Governor-General in Council has exempted raw caoutchouc from the customs duties to which it is liable under the Indian Tariff Act, 1875.

We are asked to announce that the Directors of the Crystal Palace Company have intimated to the Bengal Chamber of Commerce their intention to hold an International Exhibition next year (June to October 1881) of wools, woollen manufactures, and allied industries. The Company's prospectus and regulations may be seen at the office of the Bengal Chamber.

A large number of articles have been sent to the Melbourne Exhibition from the North-Western Provinces, including glass, pottery, carpets, mattings, stone-ware, silk, embroidery, jewellery, fibres, oils, and leather manufactures.

The report of the Royal Botanical Garden, Calcutta, for 1879-80, is more than ordinarily interesting, considerable attention having during the year been bestowed on paper-making materials. This is a subject which must command increasing attention. The demand for paper is steadily increasing in a much faster ratio than is the supply of material for paper stock. This cannot fail to raise the price of paper, and we do not think that the public will willingly submit to an increase on the price of its literature. Hitherto, several astonishing improvements in machinery have equalised the increase in the price of rags and grasses used for paper-making. There is, however, a limit to this, and a time must soon arrive when the price of paper must rise, or the cost of making it fall. There are doubtless many materials from which paper stock could be made, none in our opinion superior to bamboo, about which we have already had something to say.

The plants experimented upon at the Botanical Garden, were principally confined to several varieties of coarse grasses common, on the Orissa coast, as compared with Esparto. The best were those named respectively *Tiansi* and *Ranikharia*, and it is proposed to obtain samples in sufficient quantity for transmission to England for the purpose of further and more exact experiment. The cultivation of *rhea* resulted in failure. The crops raised were not by

any means good, and it was decided that the climate of Lower Bengal was unsuitable. This plant grows to perfection in the North-Western Provinces, and some very fine crops have been raised in Debra Doon. The Gangetic delta, too, has been found fatal to the *Eucalypti*; several varieties having been tried, and all turning out manifest failures. The pará rubber (*Hevea Brasiliensis*) and the ceara rubber (*Manihot Glaziovii*) were both tried, the latter with success while the former proved a failure. As we have remarked previously, there does not seem much good in struggling with these exotic rubber plants, when we have the common India-rubber (*Ficus Elastica*) with us. It is a hardy plant, and yields a good rubber, which would perhaps fetch as high a price as the Brazilian varieties, if the rascally native collectors would not adulterate it with mud and pebbles. The experiments made with the several trees containing an excess of tanning material served to bring prominently forward the virtues of the Diri Divix (*Cæsalpinia Coriaria*). This tree yields a large weight of pods annually, and those contain a heavy percentage of tannin.

A vast amount of good must be done by the distribution of plants from these gardens. Last year the total number distributed aggregated 19,447, and, as a large number of these may be presumed to have lived and flourished, we have a fair idea of the good work done. Besides these, 6,457 packets of seeds were distributed.

The same report gives some account of the various coarse grasses from the Orissa coast, which are said to be suitable for the manufacture of paper. It seems that after boiling, washing, and exposing to the air in the usual way, the grasses gave the following percentages of clean material, 43·79, 39·0, 46·1, 47·4, 37·1, 39·0. Of these *Ranikharia*, yielding 46·1 per cent., and *Tiansi* yielding 39·0 per cent. are the best. Out of 25 experiments with *Esparto*, it was found that the highest yield was 47·2 and the lowest 39·5 per cent., and Mr. George King, the Superintendent, is of opinion that if the two grasses above-mentioned can be obtained in large quantities and at the same price as *Esparto*, it is worth while conducting experiments with them on an extensive scale.

Mr. St. George Tucker, writing to the *Times* about the Famine Commission Report, says he believes it will be admitted that Government has at present no idea of the stores of corn in India, of the amount of stocks of food in each districts. Its first duty he says, is to ascertain and to publish to the world information on this subject. Corn is not an article which can be secreted like gold or jewellery. District officers in India have never found any difficulty in ascertaining the stocks of corn when their inquiries have been conducted with judgment and discretion. Of late years Government has discouraged the publication of information regarding food stores, partly by octroi taxes and partly by its unaccountable love of secrecy. Honest traders cannot be expected to lay up stores of corn in towns unless they be freed from octroi taxation, and be assisted by Government with true information on the subject of the corn trade. They have of late years been making the most of their profits by exporting corn. The report of the Famine Commissioners teems with remarks regarding the prolonged duration of high prices caused by the exportation of food. In paragraph 184 the Commissioners have stated their opinion that 1½lb. per diem of the meal of the common, coarser, grain suffices for an ordinary adult male who is made to work. As the lowest wages of an unskilled labourer are 4lbs. of corn a day, Government would be driving a hard bargain to expect to obtain a day's work for 1½lb. Mr. Tucker, with all submission, urges that able-bodied labourers on relief works should receive 4lbs. of corn for a day's work, and that they should be paid in corn, and not in coppers. What is the use, he asks, of giving pennies to men who must go to the shops of forestallers, who have bought up the local stores and sell at three times the usual price?

The *Times*, discussing the future of India, urges that the best chance for the material progress of the country is that she should attract capital, and it is argued that Indian tea and Indian wheat might be exported in much larger quantities if the capital employed were in any sort of relation to the productive power of the soil. In the face of the recent heavy losses sustained by those who have invested capital in the development of the agricultural resources of India, these observations lose much of their practical value. Nevertheless, most people will agree with the writer in the *Times* when he says:— "To what extent India can become a manufacturing country remains yet to be seen, but there is no doubt whatever as to the almost infinite fruitfulness of her soil. She can produce for the whole world, and she can produce well-nigh everything. Mr. Bright has declared that Indian Government does not favour the investment of private capital in the country. If there is any truth in the remark—and it is certainly not borne out by any instance he has given in proof of it—it will be for the Government of which he is a member to make sure that so mischievous a policy is no longer persisted in. We have had proof lately of the confidence which French capitalists have begun to feel in the future of India. That an Indian loan should have been taken up firm in France is an encouraging fact as far as it goes. But much more welcome would be a sign that France was looking to India herself, and not to the Indian Government, for the employment of her surplus capital in search of an investment. . . . The real thing to be done is to give the world confidence in India, so that money will flow into the country and find its own investment there. This will be a safer and more effective stimulus than any encouragement by the Government of one form of industry or another, or that any increased expenditure on these 'reproductive public works' to which, largely aided by a lavish military expenditure, the present indebtedness of India is in no small degree due."

With reference to the operations of the Nagpore Farm, which we review elsewhere, and regarding the advantages of mixed crops, we find the following in the *Englishman*:—

"This reminds us of a singular circumstance brought to our notice some years ago, and which we know to be reliable. A resident in Rohilkund, passing on horseback by a wheat field, caught sight of a rather diminutive plant on the outskirts of the border. Striking it with his whip, a quantity of milky juice spurted over his face. Being of an inquiring turn of mind, he examined the plant closely, and found it to be laden with small seed, from which, by a slight pressure, a considerable quantity of oily matter exuded. He questioned the cultivators about the plant, and was informed that it always made its appearance in their wheat fields, and that all attempts at eradication had failed; in fact they regarded it as a most troublesome, worthless weed. At his request the villagers collected a large quantity of the seed for a trifle; he had it crushed as well as the appliances at hand admitted, and sent it down to Calcutta, where it realised a sum sufficiently large, as a paint oil, not only to repay all cost, but to leave a good margin for profit. Encouraged by this first attempt, he rented in the following season a large piece of ground, which was most carefully tilled, and on this he sowed the seed closely. Not one germinated; whilst in the neighbouring wheat fields it came up, as usual most thickly! He was warned by the people against any attempt to grow this "weed" alone. He put no faith in their assertion, but the result proved its correctness. The weed in fact exhibited such a wonderful sympathy, so to speak, with wheat, that it would not grow without it! This is a bare narration of facts. Perhaps some of our readers may be able to corroborate the facts from their experience, and offer some explanation of them. The weed in question is known to botanists as *Euphorbia Dracunculoides*."

The necessity of giving sound instruction in the science of agriculture to the natives of this country is demonstrated by the *Bombay Samachar*. It is of opinion that the exhaustion of the soil owing to the ignorance of the Indian agriculturist is a calamity more dangerous to this country than famines, and believes that a widespread substantial movement to trained native youths in agriculture is the only means of bringing about a better state of things. The Madras School, the opening of small classes in the Bombay Presidency, and the founding of an insignificant number of scholarships as recently done by the Bengal Government cannot be expected to meet the great requirements of this country as regards the general improvement of its agricultural pursuits and conditions, and the *Samachar* ardently wishes to see a broad scheme in this direction inaugurated.

One of the most important commercial questions of the day in which the Punjab has considerable interest, is the condition of the wheat trade. This year the importations of American wheat into the United Kingdom will certainly be much larger than in any previous year, but latest reports of the prospects of the harvest in England are very favorable, with the result that prices have fallen and American wheat cannot be sold at the prices asked. As, again, English farmers are all in want of money, they will force their wheat on the markets as soon as it is gathered, and a further fall in prices is anticipated. Under these circumstances the prospects of realising good prices for Indian wheat diminish considerably.

In an article upon the Kurrachee harbour, the *Civil and Military Gazette* remarks that it is frequently argued that Bombay must

always be the principal seaport on that side of India, but the real question is whether there is room for both. It seems to be assumed, says our contemporary, that Kurrachee can only thrive by diverting trade from other quarters, so there will be no advantage, as far as the country at large is concerned, in the partial substitution of one seaport for another. We put the plain question—has the trade of Bombay been any the worse for the fact that the trade of Kurrachee has been multiplied almost a thousandfold since 1840 ? The diversion that will take place will be for the advantage of the country, in so far as it will mean a cheaper and speedier route. But that diversion can only proceed to a certain point, and for the rest, the chief function of Kurrachee will be to afford an outlet for a large and progressive traffic, for which hitherto there has been no opening. The Candahar province possesses great commercial capabilities. So does the Herat district—"The Granary of the East,"—as historians have called it.

THE *American Agriculturist* thus gives the development of the resources of the United States during the last twenty years :—

		1860	1880
Corn produced, bushels	...	838,792,740	1,450,000,000

IN his review of the maritime trade of British India with other countries for the official year 1879-80, Mr. Conor remarks that "whisky has replaced brandy to a great extent among Anglo-Indians." Beer too, he says, is gradually giving way to whisky. India last year imported 301,000 gallons of whisky and gin, this amount being mostly whisky. The average importation used to be 185,000 gallons. The beer trade both in imported and Indian-brewed beer, is showing signs of a decline ; though, with the hill beer, this was chiefly due to so many of the troops being in Afghanistan. The trade in wine is also declining.

THE Department of Finance and Commerce has just issued its first review of the External Land Trade of British India, covering the Import and Export Frontier commerce from Sindh to Burmah. When it is remembered that the frontier of British India extends over upwards of 5,300 miles, there will be no difficulty in assuming that the report is necessarily voluminous. In future, however, a quarterly, and eventually a monthly issue is promised, which will bring the facts much more within the scope of careful examination and the service they are so well calculated to render to the commerce of this country. The review is elaborate, almost in the extreme. We must therefore, for the present be content to reproduce only those statistics which have reference to our more immediate neighbours. From the Hubb river, near Kurrachee, the frontier extends in a northerly direction for about 1,800 miles, separating Sind from Beluchistan, Khelat, and Afghanistan. Pursuing its tortuous deviations, it divides the Punjab from Cashmere and a part of Thibet. The frontier of the North-Western Provinces and Oudh divides those provinces from a portion of Thibet and Nepal. Thence follow the frontiers of Bengal, Assam, and British Burmah. Notwithstanding the great difficulties by which it is attended, the amount of trade between Sind, Northern and Southern Beluchistan, and Candahar is considerable, and may be expected to increase when it shall become possible to discard the Bolan Pass for the new railway. The following figures will show the depressing effect that warfare has had upon trade. From this, however, we may hope that it will in time recover. The total amount of Imports and Exports in the past year with Beluchistan was only Rs. 16,45,943, whilst in the previous year of 1877-78, it sums up to Rs. 22,90,768. With Afghanistan also, the amount fell in the past year, though not so seriously. Against a total of Rs. 1,85,00,717 in 1877-78, the amount in the past year was but Rs. 1,49,88,783. The total of this trans-frontier trade for the years 1877-78 and 1878-79 is Rs. 3,35,09,807 and 8,85,37,193 respectively. In the former years the excess of imports over exports was nearly 29 lakhs, and the latter year, nearly 60 lakhs.

MR. WILLIAM HOEY, C.S., has lately published "A Monograph on trade and Manufactures in Northern India," and of it the Lahore paper observes, "a pamphlet more replete with the most valuable information on the subjects of its treatment, it would be impossible to produce."

BOTH Messrs. Moran and Messrs. Thomas & Co. adhere to their former estimate of 22,000 maunds as the outturn of indigo in Lower Bengal this season. As regards Behar, the former gentlemen tell us "the weather on the whole has not been altogether favourable, the rainfall having been again heavy, and, in addition, the plant has been attacked by caterpillars in great numbers, and a good deal of fine *khontee* plant has been destroyed by them ; our last advices are somewhat better, the weather having cleared a little and produce showing some improvement. Most factories are now at work with their second cuttings, and in another fortnight we should be able to form some idea of what the total outturn is likely to be." Messrs. Thomas & Co., say that "accounts from the Benares Provinces are generally less favourable, and we fear the result of the season will be under planters' expectations. As regards the Doab, the complaints of drought have been general. There are reports by telegram of showers having fallen, but they appear to have been more or less partial and light, and more rain is anxiously looked for. Produce so far has been decidedly good, but it is impossible to form any idea as to what the outturn may be."

THE last issue of the *Moniteur Official* of Pondicherry contains a letter from Mr. C. Poulain, taking Mr. King, of the Geological Survey, to task for some alleged errors committed by him in his report on the Artesian Wells at Pondicherry. Monsieur Poulain claims to have given his attention to the boring of the first Artesian well in India, not for the purpose of feeding the boilers of the steam engines used at the Savana Spinning and Weaving Mills at Pondicherry, but for the purpose of irrigating paddy fields. So far back as the 28th November 1876 he applied to the Pondicherry Government for a grant-in-aid ; and in the petition that he then presented, this object is clearly set out. It was not at random that he proceeded ; nor is his success to be attributed to a fluke. From a minute scrutiny of the papers published by the Geological Survey, he made sure that water bearing strata existed, which dip eastward from the higher levels lying west of Pondicherry. He concludes by thanking the Duke of Buckingham and Chandos for having taken up the subject of Artesian Wells, and he considers that the enlightened interest evinced in this cause by Monsieur Laugier, Governor of Pondicherry, entitles him to rank among the benefactors of that city.

THERE is no disputing the fact, says the *Englishman*, that by one plea or another the Government of India has of late years exhibited an increasing tendency to enter into competition with private capital and private manufacturing and commercial enterprise. On all sides the operation of the same vicious and anti-economic spirit, which seems to have received a sudden stimulus from the new railway policy of the Government, is visible. Educational institutions are perverted from their legitimate limits and purpose into mere nuclei for gigantic manufactories, the shadow of which acts as a blight upon private enterprise The jails of the country from being penal institutions, have been converted into great industrial centres, the inmates of which are comfortably provided for in return for a tale of work which would not support them outside, and the outturn of which, being produced by labourers whom, in any case, the Government must feed, can be put on the market at prices which defy private competition. In the Postal Department it is not above collecting tradesmen's bills for a consideration ; on the plea of encouraging poor people to accumulate small savings, it has covered the country with State Banks, which angle for the accumulated savings of the well-to-do and the working balances of traders, by offering higher rates of interest than the private banker can afford to pay. Our Chambers of Commerce and Trades Associations have been content to look on in absolute and apparently unconcerned silence, till the scandal has become one which affects their reputations hardly less than that of the Government itself.

A SHORT time back it was brought to the notice of the local Government of the existence of a new plough, tried very successfully at the Cawnpore farm, which it would be very advantageous to introduce into Mysore, with a view of practically shewing

the ryots its superiority over the present country plough, as its characteristics and capabilities stamp it as the one to supersede all others now in use, American or English. The Mysore Government have thought so well of the plough (the "Kaiser") which is extremely simple in design and construction, that two have been ordered from the Cawnpore farm.

THE Burmah rice trade this season has hitherto been, and gives promise of continuing, in a flourishing state. The customs duties from the various ports of the province during August, under the head of exports, have exceeded, by over a lakh, similar duties in the same month of 1879, and the increase is due in the main to unusually large shipments of rice to foreign countries from the three ports of Akyab, Bassein and Rangoon.

AMONG the reports received from the British Consuls in China with reference to the consumption of Persian opium in the various consular districts, is one from the British Consul at Taiwan, who states that the careless way in which Persian opium is prepared and packed, has already seriously interfered with its sale. For this reason great risk attends all dealings in the article; no two chests are alike in quality, and frequently two or three descriptions of drug are found in the same chest. Dealers are, therefore, suspicious, and examine every chest carefully, and money, it appears is often lost on the sale.

THE Persian correspondent of a contemporary says that Persian opium from the crops of 1880 is being brought daily into Bushire for shipment. The S.S. *Bengal* carried away 113 chests, principally for London. The S.S. *Calder* left on the 25th instant, with 805 chests, of which 743 chests were for China, and the residue for London. The *Calder* proceeded direct to Galle, where her cargo will be transferred to the P. and O. steamers. It is given out that the Indian Government are making arrangements for the levy of a duty of Rs. 100 per chest by the Ceylon Government, similar to that stipulated for Bombay, Kurrachee, and Aden. If this measure be adopted, the Persian merchant will have to arrange for direct steam carriage to China to enable him to compete with the Indian opium.

IT is stated in a recent proclamation of the Governor of Chekiang (China) that there are enormous areas of land left uncultivated in his district, and that, although 17 years have elapsed since the last war which so terribly ravaged the country, a large extent of land has never been able to pay the taxes, and has consequently been left untilled. This is particularly observable in the departments of Chinhoua, Chuchow, and Yen-show, in which upwards of 1,600,000 acres are idle; while in those of Hang-show, Ka-shing, and Hu-chow, there are 6,000,000 in the same predicament. Some of the land is too poor even to return much for labour and capital bestowed upon it, but there are at least 5,500,000 acres of really rich and fertile soil at present completely neglected. This arises partly from the fear lest any cultivator of the land in question should be called upon to pay up the arrears of taxes; but the Governor's proclamation specially mentions this exemption.

THE following is a translation from the *Chiugai Bukka Shinpo*:—"Cotton yarn is a principal import into Japan, and the purchases usually amount to between five or six hundred thousand to eight hundred thousand *yen* monthly. This valuable commodity is chiefly imported by foreigners, not more than ten per cent. being imported by Japanese. The business is therefore, under the control of the former, and consequently always unfavourable to the latter. Five native merchants desirous of changing this state of affairs, have subscribed a capital of one million *yen* to form a company to trade in yarn direct with foreign companies, in order to evade the officious intermeddling of foreign merchants (in Japan). This is the only way of restoring our commercial rights, and we ought to congratulate ourselves upon the action of the five merchants."

THE agricultural statistics of New South Wales for the year ending March 31, 1880, show that the extent of land under cultivation was 489,404 acres freehold, and 145,800 acres leasehold; and the extent of land enclosed and not cultivated, was 16,106,396 acres freehold, and 1,471,793 acres leasehold. The extent of land unenclosed was 3,982,642 acres freehold, and 524,930 acres leasehold. The total extent of holdings was 20,579,078 acres freehold and 2,142,524 acres leasehold. Of wheat for grain there were 233,869, acres, and 25,280 acres for green food. Of maize there were 135,034 acres grown for grain, and 2,145 acres for green food. The total amount of wheat produced was 3,613,266 bushels, maize 4,761,856 bushels, and barley, 131,541, bushels. There were 3,091 acres of vineyards, and the total number of oranges produced was 2,763,811 dozens. Of sugar, 17,229,296lbs. were produced. The returns, as a whole, show that agriculture is progressing rather slowly, although the averages of the yield of crops compare very favourably with those of other colonies of the continent. The live-stock statistics are not yet published. It is confidently expected that they will disclose great increase in all classes of stock.

THE discovery of a new fibre in Mexico, called "Pita," which grows in a wild state over large areas, is likely to prove a considerable source of trade, and of great value to the Republic. Experimental shipments to England have been manufactured, and returned to Mexico in handkerchiefs and cloth, which are described as of a beautiful color, and the material—durable and soft as silk. As industries develop in India, there are no doubt many fibres, as yet undiscovered, which will form important additions to the productive resources of the country.

Florida has a weed growing over large tracts of country, which is found to be wild jute. The fibre grows in the greatest profusion in Putnam, Marion, and Sumter counties, and also in many other districts. Hitherto, this wild jute has furnished grazing for vast herds of wild cattle, as well as for domestic herds.

Experiments are now being made, under scientific processes of cultivation, to determine the yield per acre, and the quality for manufacturing purposes of this apparently large source of new wealth to the export resources of the States.

OFFICIAL PAPERS.

TASAR SERICULTURE.

GOVERNMENT OF MADRAS.

9TH AUGUST 1880, No. 945.

FROM Major G. Coussmaker, to the Secretary to Government, General Department, dated Poona, 21st February 1880, No. 2.

I HAVE the honor to report for the information of Government, on the experiments which I have during the past year made in Tasar sericulture, and the conclusions which I draw therefrom.

1. As mentioned in my Report No. 1, of 10th January 1879, I had put by 50 cocoons of the crop of 1878 for breeding, and during the hot weather I collected in the districts, where I was, upwards of 1,000 more; several of which were good enough to be kept for the same purpose; of these I sent some away to different correspondents, and from others I got a good supply of moths, many of which I allowed to escape, as I had not sufficient food for many caterpillars. I kept the eggs from 76 moths, amounting to some, 15,000, of which I sent away one-third only, hoping I might find food in Poona for the remainder, but I miscalculated my resources and the power of protecting them from their enemies, for I was only able to secure 500 good cocoons; of these I have kept 100 for next season, and I have sent home a large portion of the remainder to Mr. Thomas Wardle.

2. In my previous reports I had mentioned that the great difficulty in rearing these worms was to ensure an unfailing supply of suitable food, and that in order to obtain this, I intended to plant my bushes in the form of hedges. Accordingly, in June, as soon as there appeared to be any promise of rain, I began my plantation. There is in my garden a convenient plot of ground about one-sixth of an acre in extent, with a southerly aspect; this I had cleared of trees and bushes, and laid out in ridges 4 feet wide with, gutters on either side; on these ridges I have planted all the shrubs which I have collected during the time I have occupied the house, and have now my hedges continuous and complete, supplementing them with more plants raised during the last six months. I have now got 340 feet of Lagerstrœmia Indica, vern. *Daiyeti*, 270 feet of Zizyphus Jujuba, vern. *Bher*, 90 feet of Carissa Carandas, vern. *Karinda*, 107 feet of Terminalia Tomentosa, vern. *Ain*, 15 feet of Terminalia Arjuna, vern. *Sadara*, and 46 feet of Ficus Benjamina, vern. *Nandruk*. Of those the *Daiyeti* is certainly the most promising, as the harder it is cut back or eaten off by the worms, the more luxuriantly it throws up shoots especially when watered liberally; these shoots are clothed with leaves the whole way up, and the caterpillars greedily devour every bit of leaf, and even the more succulent parts of the shoots; I have not been able to raise this plant from seed, but find that the roots have excessive vitality. The *Bher* is the tree on which in the Deccan the greater number of cocoons are found, it grows very quickly but only from seed, as far as my experience goes, the leaves are rather sparsely distributed, and the growth is very straggling, the caterpillars eat up every leaf and also devour the flower. The *Karinda* is more leafy than the *Bher*, and the caterpillars also eat it off very closely, but it recovers leaves slowly, and the plant does not grow quickly. The *Ain* and the *Sadara* have much larger leaves than the preceding shrubs, but they grow very slowly, at all events, for the first two years of their existence, the *Ain* is the favorite

food of the worm in the Konkan. I do not know whether it eats the *Sadura* to any extent, and as my plants are only seedlings of this past monsoon, I cannot yet give any information as to its utility. The *Nandruk* plants have not thriven well, nor did the worms feed on them this last monsoon, though on the more elevated country from Satara towards the south, I have found many on this tree, in the neighbourhood of Poona, therefore I should not recommend it for this purpose, but am in favor of growing *Daiyeti* thickly planted on ridges, so as to form continuous lines of food while the *Bher* and the *Karinda* might be planted as hedges surrounding the plantation, as they naturally grow into thick tangled masses, and being thorny would keep out cattle. In three years the *Bher* will grow from seed into a bush 4 feet high, and in the same time the *Daiyeti* raised from cuttings and root suckers would be nearly as high, and the whole plantation would be ready for feeding by the commencement of the third monsoon after it had been started. I should, if possible, lay it out with a view to irrigating it, for, though there is no necessity to water the trees during the rains, still, liberal watering and plenty of manure will always increase the supply of leaf; by high cultivation of this nature, my small plantation is now so far advanced that next monsoon I hope to be able to state how much ground will be required for a definite number of worms.

3. I regret to say that the cocoons which I sent home last year to Mr. Wardle were spoilt; I had dried them in an oven, and the fibre was burnt. I afterwards sent some home with live pupæ in them, but it was not at the right time of the year, the moths came out and spoilt the cocoons. I have, however, now prepared some cocoons carefully, and expect they will give a better result, the chrysalides having been killed by hot dry air.

4. As stated by me in a former report, I keep all my seed cocoons hung up on a wall, out of reach of rats, &c.; and find as long as they are left thus undisturbed; the moths only come out at the regular season. Last year the first worm was hatched on the 15th June and the last spun its cocoon on the 15th November. It appeared to me that as soon as the cold east winds which we had at the end of October, set in, that the worms made no further, progress, and more of them died at that time, instead of spinning their cocoons than at any other period of their existence. During the five months, I was rearing them this last season, I could not detect any epidemic nor any well-defined sickness among them, nor did their appear any difference between those reared in the open or in the shade, or on large or small trees for under cover; insects, birds, mice, rats, squirrels and lizards, carried them off repeatedly, but the great cause of so much life being lost, was that I tried to preserve more than I had food for: in fact they died from preventible accidents.

5. During this last season, I was working in the Ahmednagar districts, where I had been informed by a native official in the Forest Department that there were no Tasar cocoons to be found, when, however, in March and April, the *Bher* trees become completely leafless, I perceived that there were many cocoons hanging from the branches; by fixing a price, one pie per cocoon, and paying some small boys for every one they brought, I soon got many people to search for them, and in less than a month the men, women, and children of one village, where my camp was, brought in upwards of 1,000. This quite confirms my former experience that the insect is found nearly everywhere, and the wild cocoons are very easily obtained—in the Konkan where the rice-cultivating classes go into the forests to cut down the small branches to place on their fields and burn for manure in January and February—in the Deccan where the *Bher* tree sheds its leaves in March, April, and May. If therefore the Forest Department would always buy every cocoon offered to them (I believe two cocoons could be obtained for one pie), these might be sold annually like any other forest produce, those that are empty or injured,* should be at once put into sacks, all extraneous matter as the leaves and twigs on the outside, and the exuviæ of the caterpillars and chrysalides inside the cocoons having been first removed if practicable, for such things only harbour beetles and moths; those that are sound and heavy containing live pupæ in fact, should be hung up on walls out of reach of rats, mice, and squirrels, and if possible protected against ants as well, a window might be left open at night and then all the moths which come out of the cocoons would be able to escape. If, with a view of rearing the worms near the place where the cocoons were kept, it should be thought advisable to collect some fertile eggs, it would only be necessary to put the female moths out on bushes and trees, during the night the males would visit them, and at the following sunset the females would begin to lay their eggs. In this way a large supply of eggs can be obtained with great certainty, and during the interval of eight or nine days between the laying and hatching of the eggs, they may be despatched through the Post Office without receiving any injury.

6. By taking some such steps as these, this industry would soon become firmly established, and in a few years would develope greatly, the demand is large. I constantly receive letters from merchants in this country and from manufacturers in Europe urging me to ensure a steady supply. I may here mention that within the last month, M. Daniel of St. Etienne, a ribbon manufacturer, has written twice to Messrs. Troncher & Co., asking them whether they could engage an agent for him to collect cocoons in this presidency. I have had these letters in my hands and have communicated their contents to the Conservator of Forests, Northern Division, asking him whether it would not be possible to stimulate the collection.

7. One of the most interesting and I think important facts that I have this year been able to prove, is with regard to the composition of the cement with which the caterpillar hardens its cocoon. Former analyses of this agent made for me in England by Dr. Taylor, and in Bombay by Dr. Lyon, had shown that it contained the acid urate of ammonia, that it was in fact excrementitious, and this year by opening the cocoons at various intervals, I was able to convince myself of the fact that when the caterpillar has left off feeding and begins to spin, it voids the food remaining in the alimentary canal, first of all in a more or less solid form and of a dark color, but after it has become fully enveloped in the cocoon, the excrement comes away as a light colored liquid, the hue and consistency of which depend upon the amount of vegetable matter not previously evacuated, and the amount of lime, carbon, and ammonia present; the respective proportions of these ingredients vary, I presume, with the food on which the caterpillar has fed and with the state of the atmosphere at the time of spinning, also the longer they remain coating the fibre, the harsher and more discolored it will be; it is therefore very necessary, I think, to remove this cement at a very early date, and this, chemistry has shown the manufacturers how to do; judicious feeding too may alter its nature. Before long fresh cocoons will be at an early stage thoroughly cleansed of all discoloring matter, and Tasar silk will be available for manufacturing purposes as colorless as it is when first put forth by the caterpillar.

8. Besides the small experiments which I made this last season in Tasar sericulture, Mr. Stormont, the Superintendent of the Khandeish Experimental Farm, tried to rear some of the worms; at first he met with several difficulties, but these he gradually overcame and gathered a few very good cocoons out of the first crop, the second promised very well for some days, but just when the worms reached maturity, the weather proved very unfavorable, and from one cause or another he did not succeed in getting a crop; next year we hope for better results. Some fine cocoons were gathered in Dharwar, and in Uran from seed supplied by me. Mr. Natu, an Inamdar of Poona, has several times come to watch my method of cultivating the worms, and he assures me that he intends to do the same. Mr. Baird, on behalf of the Maharana of Udepur, has lately called on me for the same purpose, and he tells me that he believes that the Maharana will also start a plantation. Through the kindness of my correspondent in the Santhal country, I have procured a few cocoons of the large or *Chuttisgarhi* variety of the Tasar moth, and as this crosses readily with the small or *Desi* variety, which only is found in the Southern Maratha country, I hope next season to procure larger cocoons than I usually do.

9. I had Rs. 283-13-11 remaining (out of the money granted to me in 1875 for Tasar experiments) at the commencement of last year. This has now been expended in purchasing cocoons, in forming the plantation already mentioned, in despatching cocoons and eggs to various correspondents, and in paying for the manufacture of silk yarn from cocoons as stated in my Report No. 9, of 20th November 1879. The account has been submitted to the Accountant-General. If Government will place the further sum of Rs. 500 at my disposal, I will continue to purchase cocoons from the villagers in the districts where I may have to work, and will carry out more experiments.

From R. W. Morgan, Esq., Deputy Conservator, Wynaad, to Colonel R. H. Beddome, Conservator of Forests, dated Manantoddy, 24th May 1880.

With reference to your Endorsement No. 198, of the 17th instant, on G. O. No. 479 of the 28th ultimo, I have the honor to state that I have been continuing my experiments with the Tasar silk-worm.

2. After attempting in vain to procure cocoons in this presidency, I tried Bengal, and in April received 275 from Simla. The moths commenced to emerge at once, but the sexes refused at first to unite. This perhaps was owing to the elevation, some 4,500 feet,* but after a time a few couples did. The average number of eggs laid was about 270.

* This is a mistake, Manantoddy being only about 2,700 feet—R. H. B.

3. I noticed that the females were of two distinct types—one being of a rich golden tint, and the others a warm brownish-grey. This latter type varied considerably, some having a reddish tint, whereas others inclined to buff; the males, however, which were invariably smaller than the females, were of a deep chocolate-lake in color, occasionally having a slightly golden or purplish tinge in the wings.

4. The copulation lasted for from 20 to 30 hours, and I noticed that the males never mated again, unlike the mulberry silk-moths. The fertilised females were removed into a muslin-covered box in which they laid their eggs on twigs of *Eugenia*. On an average they lived about 10 days. The eggs were hatched in from 10 to 15 days. I placed the young worms in a large case covered with muslin, in which there was a tin-box filled with wet sand, and stuck full of the young shoots of *Careya arborea Eugenia Jambolana*. Finding they preferred the latter leaves, I fed them entirely on them. On the seventh or eighth day they cast their skins for the first time.

5. The oldest caterpillars were hatched some 39 days ago, but are only one inch in length. This has not been from starvation, for they have been fed liberally and look quite healthy, but I fancy on account of the exclusion of sunlight which is essential to their well-being. The last 10 days I have been feeding them on *Lagerstrœmia* (Venteak) which they prefer to *Eugenia*.

6. I have placed several worms out on trees in my compound, but have slight hopes of their escaping their numerous enemies.

7. The total number of caterpillars of various ages in my possession at present is about 2,000, but it can hardly be expected that the whole of these should reach maturity. They are very troublesome to manage on account of their wandering propensities, and you can scarcely open the box they are confined in for a moment without their swarming out all over the place. They maintain their hold with such extraordinary tenacity that they will suffer being torn in two before they relax it. This makes it very difficult to shift them.

8. The moths almost invariably escape from the cocoons through the up or pedicel end, but I find that about 2 per cent. of my cocoons have been pierced at the lower end.

9. In this district the Tasar is but sparingly found, though the climate is undoubtedly suited to it. I have found cocoons here as large and larger than any I have seen from the North. The moths here seldom or never lay more than one to two eggs on each tree. There are two crops of cocoons in the year—one in May and June, and the second in October. In this latter the moths do not seem to escape till the following April, lying dormant the six intervening months. This, no doubt, is due to the forests in India being deciduous; for the eggs if laid would be lost through the falling of the leaves to which they are attached, and even if they managed to escape this peril and were hatched, the young would speedily die from want of proper food.

10. The Wynaad contains a vast area of forest more than half the trees of which are capable of feeding silk-producing caterpillars. The whole of this is wasted, for although the climate is favourable to insect life, yet its enemies are sufficiently numerous to more than keep it in check. Attempting therefore to breed silk-worms in a state of Nature, will, I fear, never pay in this district, for though we may protect them from a host of their destroyers, yet there are some, such as the various species of the *ichneumon* flies, against the incursions of which I cannot see any possibility of guarding. To breed them however under cover, and in a state of partial domestication is feasible enough, provided the building devoted to that purpose is thoroughly lighted and ventilated, and means devised for preventing the worms from indulging their wandering propensities. If the breeding-shed were made portable, it would no doubt, be a great advantage, and this might easily be done were it constructed of wood; it could then be shifted (the supply of leaves being exhausted) from one spot to another.

11. I had hoped to have tried experiments on a larger scale than I have hitherto done, but find that, owing to my frequent absences in the district, the caterpillars are neglected and die.

12. So great an amount of constant care and attention is necessary for the success of an experiment like this, that a single day or hour's carelessness may render futile the patience and trouble of weeks. I have therefore determined to wait until September next, when I mean to devote a considerable portion of my furlough to experiment and to start a breeding establishment.

13. I have not been able to procure the *Cricula trifenestrata* cocoons you asked me to send to Dr. Bidie, for, though I have obtained a great number of them from Coorg and its neighbourhood, the whole almost proved to have been destroyed by ants and *ichneumon* flies.

14. *Careya arborea* trees, however, are loaded with young caterpillars, and as soon as the cocoons are spun, I will send Dr. Bidie any number.

OPIUM IN CHINA.

(From the Press Commissioner.)

FROM E. L. Oxenham, Esq., Her Britannic Majesty's Acting Consul at Wu-Hu, to the Under-Secretary to the Government of India Financial Department,—No. 36, dated Wu-Hu, 15th October 1879.

In conformity with your letter No. 238, dated Simla, the 4th May 1871, I have the honour to forward the Annual Report on Opium for the Port of Wu-Hu for 1878-79.

Opium appears to be but scantily grown in the southern portions of this province, An-Hui, where the ground is chiefly devoted to the cultivation of rice. I am, however, informed that in the district of Kuang-Te-Chow, in the extreme south-east, small quantities are grown for local and individual consumption on spare patches of ground not required for ordinary crops. This district was depopulated during the T'aip'ing rebellion and is now chiefly inhabited by poor immigrants from other provinces, who, destitute of money, can only obtain opium by growing it themselves. They do not, however, rely on it as a source of livelihood, nor is the cultivation likely to increase to such proportions as to sensibly, affect the importation of the foreign drug.

In the more northern portions of An-Hui, where cereals are chiefly grown, in the districts of Po-chow, Shou-chow, Ying-chowfu, Tong-Yang, and Su-chow, the poppy is extensively grown, and regarded by the people as a source of profit. An eye-witness informs me he passed through many acres of country covered with the poppy. The rows of plants were very irregular, the ground only partially weeded, and the cultivation generally careless and slovenly, offering a marked contrast to the neatness and care displayed in growing a similar crop in other provinces. This want of care displayed may be due to the recent introduction of the plant into the province, and lack of knowledge of the proper methods of cultivation.

Cultivation of opium is strictly prohibited, and proclamations against it are to be seen in all large cities. Within five or six miles of the cities no poppies are visible, but beyond that radius opium is openly grown without incurring official interference. The cultivation is increasing, and is likely still further to do so, if the severe measures now directed against opium growing in Shan-Si remain long in force. The crop this year was an excellent one. This native-grown opium is all sent north to the provinces of Ho-nan and Shan-Tung, some of it, I understand, finding its way to the Treaty Port of Chefoo. None is sent to Wu-Hu.

* * * * * *

I append a table giving the import of opium for the last three years. Wu-Hu was opened to trade in April 1877:—

	1877, Nine months.	1878.	1879, January to September.
	Piculs.	Piculs.	Piculs.
Malwa	1,157	2,325	2,170
Patna	2	2	10.80
Benares	......	......	3.80
Persian	......	1	70.50
TOTAL	1,159	2,328	2,255.10

The prices at present ruling for opium here are—
Best Malwa, taels 560 per picul.
Persian „ 430 „ „
Patna „ 410 „ chest of 120 catties.
Benares „ 390 „ „ „

A large increase in Persian opium will be noticed. No native opium being used, the demand arising for cheap opium is to a certain extent satisfied by the lower priced Persian, the flavour of which is at the same time more palatable than that of Patna or Benares.

* * * * * *

From A. W. Hewlett, Esq., Her Britannic Majesty's Consult at Canton, to the Under-Secretary to the Government of India, Department of Finance and Commerce,—No. 57, dated Canton 2nd April 1880.

1. An abundant poppy crop has been gathered in the provinces of Sze-chuan, Yunnan, and Kweichow. Little is known in Canton regarding the yield in Shen-Si, Kan-Su, and Manchuria; but it is believed that the prohibitory measures taken by Tso Tsung-tang have considerably hindered cultivation of the poppy in the provinces of Shen-Si and Kan-Su.

2. Nothing is known of what is likely to affect the outturn (*i.e.*, the quantity of crude opium yielded by the crop).

3. Cultivation of the poppy is generally believed to be on the increase. No opium is grown in the province of Kuangtung.

4. During the year before last, 1878, *i.e.*, Kuangsu, 4th year, proclamations against the growth of the poppy were issued generally throughout the empire. The effect of those, however, has only been to diminish cultivation in districts situated close to official residences, outlying districts being as thickly sown with the poppy as before.

* * * * * *

The following table has been compiled from the statements of an opium-smoker, who spends $5 a month, out of a salary of $10, upon opium. The average value of the dollar for 1879 was 3s. 8d.

	Price the ball or package of 48 Chinese ounces.	Amount of prepared opium after boiling.	Amount of taxation, the ball in Canton.	Amount of dealer's profit in Canton, each ball.	Cost of each Chinese oz. of prepared opium.
	$	Chin. oz.	$	$	$
Malwa	24	38	3 20	0·80	0·66
Patna	18*	28	3 20	0·80	0·83
Chinese	...	..	3 20	0·80	0·50

* *Note.*—The ball of Patna weighs from 44 to 48 Chinese ounces.

A.—One advantage of Malwa is that it can be cut up, and consequently sold by the ounce in an unprepared state. It is the favourite opium in the Swatow and the Ka-ying (or western) parts of the Kwang-Tung Province. Eighty per cent. of the people around Canton smoke Patna, and ten per cent. Chinese opium.

B.—Malwa produces more prepared opium than does Patna from the same weight of the unprepared drug. All opium smoked on the mainland is boiled on the mainland. The farmer's monopoly at Hong-Kong makes prepared opium but little cheaper there than at Canton.

C.—The precise taxation now laid upon opium was explained in Mr. Hance's Despatch No. 70 of the 19th of April 1879. The boiler's tax (local) is $0·4½ the ounce of prepared drug. See Mr. Hance's Despatch No. 103 of the 20th June 1879.

D.—The prices, each ounce, are retail prices: 28 ounces of prepared Patna cost about $21 in Hong-Kong and $22 in Canton. The ball of unprepared opium is now about $2 dearer than it was two years ago.

E.—Chinese opium is said to have a "fishy" taste. The leaves in which Patna opium is wrapped, are sold and boiled down.

7. Foreign opium, other than Indian, is rarely imported at Canton. Small quantities of Turkish and Persian opium, however, are brought annually to Shanghai.

* * * * * *

From A. W. Hewlett, Esq., Her Britannic Majesty's Consul at Canton, to the Secretary to the Government of India, Department of Finance and Commerce,—67, dated 11th May 1880.

In compliance with instructions which I have received from Her Majesty's Minister at Peking, I have the honour to enclose a report relating to the consumption of Persian opium within this Consul district.

PERSIAN OPIUM.

1. It is stated on turstworthy authority that not more than about 4 piculs of Persian opium were imported into this province last year, but none as yet this year. This opium is chiefly consumed in Hui chonfu, west of Canton. The consumption in this part of China therefore being so limited, cannot be held to affect seriously in any way the position of other kinds of opium. For some years past the annual importation has ranged between 4 and 9 piculs.

2. A few years ago the sales of Persian opium in this province used to affect Indian opium on account of its cheap cost; but, as it was found a very profitable trade to Persian importers, great competition sprung up, and consequently its lay-down price was quickly raised, and importers were at last unable to sell at lower rates than those ruling in the case of Bengal opium, so that both kinds were kept at nearly equal rates, and the sales of Persian gradually fell off.

3. Persian opium made its first appearance in the Chinese market about ten years since. The "touch" of this opium is about 80 or 70, and it is most liked in Formosa, where the Chinese prefer it to Benares opium. The first five or six years the quantity imported was very moderate, *viz.*, about 1,200 to 1,500 chests annually, each chest weighing 1 picul, but of late the arrivals have increased at the rate of 2,000 to 3,000 chests a year. This year the import may be estimated about 8,000 to 9,000 chests. Half the quantity is required for the Formosa ports, and the balance is consumed in Shanghai and the north, partly on account of the high rates ruling there for Malwa opium, and also in part because the drug in shape, color, and touch is made to resemble Malwa opium.

Persian opium comes free of duty; consequently it pays the Persian importers well. As on our opium a duty of Rs. 750 per chest or picul is levied, it will pay Persians to sell at rates as much as $350 per chest below our opium prices. The price of Persian generally depends upon the price of Malwa and Bengal opium, and usually keeps on an equal footing with them.

E. H. PARKER.

SELECTIONS.

DR. CENTER AND BRIGHAM YOUNG ON *REH*.

SOME years have passed since Dr. Brown of the Lahore College, wrote a valuable paper on the manurial treatment of *reh*, the saline efflorescence which is the curse of Indian soils. The same subject has again been attacked by a gentleman who possesses the reputation of being the cleverest analytical chemist in India, Dr. Center, of the same institution. Dr. Center has added to his many distinctions, by putting under requisition a no less remarkable authority than Brigham Young, whom he visited in the course of his rambles round the world, and with whom he smoked many a friendly pipe, whilst the Professor furnished all the science, and the Prophet all the rule-of-thumb. "There is," said the Prophet, "salt in everything. Water has salt; plants have salt; and earth has salt; and the Bible tells us that if the earth have lost its salt it is useless." Mr. Young, however, hinted that Providence rather overdid it; and accordingly, both he and his Mormon community had taxed their wits to discover some means of circumventing Nature's overflowing bounty. Their simple and effective methods of relieving the Utah soil of its superabundant salts are described at the end of Dr. Center's paper, and some of them will be quoted further on. Meanwhile we may refer briefly to the author's account of the formation of saline efflorescene in soils.

The oldest and perhaps most popular theory of its origin is the marine theory. According to this hypothesis, "The Indo-Gangetic depression was considered to be an old sea-bed, the soil of which became impregnated with salts from the existence of shallow *runns* and lagoons in a former geological age." Now there is some evidence that the Punjab plain was once covered by an Eocene sea, bounded by portions of the outer Himalayas, and penetrating the mountains as far as the valley of the Upper Indus. However, the theory of recent marine impregnation, at all events, has been abandoned; and it has been established that "the whole of the materials of the Indo-Gangetic basin are fresh water alluvia to an unknown depth, and consist, in fact, of the *débris* of the Himalayas carried down by its drainage." Dr. Center tells us that borings in the Umballa district to seven hundred feet; in Calcutta to four hundred and eighty; and at Rajanpur to four hundred and eighty-four, have shown nothing but fresh water alluvium. The causes of salinity in soils have been only those which are still in operation, such as the decomposition of mountain rock, and of the more or less comminuted *débris* of the plains, by the action of water, light, and carbonic acid contained in the atmosphere, and in the pores of the ground. Dr. Center traces all the cunning, intricate processes, with the patience and the loving familiarity of an Isaac Walton discoursing on fishes and fly-hooks.

The soluble substances produced by rock decomposition are remarkably uniform in their nature. The main ingredients are carbonates of alkaline earths, chiefly of lime; and alkaline chlorides and sulphates, chiefly of soda. Of salts of this description, the Ravee, Jhelum, and Indus contain from eight to fifteen grains per gallon, according to the state of the floods. The proportion of soluble salts capable of efflorescence varies from about two to four-and-a-half grains. The rain water, which contains free carbonic acid gas, acts powerfully as a decomposing agent on the soils of the plain, which consist of rock and other *débris*. The depth to which the rain and other water penetrates through the soil depends on the nature of the latter being greater of course in sandy soils and less in clayey soils. After the rains evaporation sets in, the soluable salts are drawn to the surface by capillary attraction and are finally left in the form of a whitish "efflorescence." Here is Dr. Center's more detailed explanation of the change :—

When evaporation succeeds, it draws up the moisture in the more porous surface soil by capillary action. As the water and carbonic acid pass off, the solution becomes more concentrated, and carbonate of lime is re-deposited. This last action takes place first, and as the concentrated solution is drawn up to the surface, it finally deposits its most soluble salts, on drying as an efflorescence on the surface. An essential condition is the dryness of the climate. In more temperate but dry regions, as in the Utah Basin and the elevated parks or plateaux of the rocky mountains, efflorescences appear as well as in the scorching plains of India. The action, however, is intensified by heat, which increases evaporation. By similar capillary action the moisture will creep up the sides of objects lying on the ground, such as pieces of brick, and deposit a copious efflorescence. At first it appears in glittering crystals, but as the sodium sulphate gradually loses its water of crystallization, it breaks up into a copious white powder of anhydrous salt and it is then that it is most apparent.

For an inquiry into the Mormon system of removing saline ingredients, the Prophet referred Dr. Center to Mr. Woodruff, Secretary to the Agricultural Society, and to some of the best farmers about salt lake city :—

The plans adopted were the following :—A salt field was ploughed and small runlets of fresh water were sent down the field, at short distances apart, washing the soil and running off into the drainage of the country. Another method was to plough up a field and make a terrace round it and then flood it. The water was allowed to soak for some time till it had dissolved the salt and was then run off. Another plan was to terrace a ploughed field and dig a deep trench round it. The field was flooded, and the unploughed subsoil being less permeable, the water holding the salt in solution filtered into the trench. I observed similar processes carried out on the salt marshes round the Bay of San Francisco. This is gradually silting up, and surrounding it are miles of low flats impregnated with sea salt, and growing only saline plants. Through these pass shallow delta channels, scoured by the rise and fall of the tide. To reclaim this soil, low earth embankments are raised round the farms. These are fitted with floodgates closed by the rise of the tide and opening on its fall. The salt in the soil is washed out by the fresh water of the streams falling into the bay, by a process of sluicing such as I have described, and is run off as the tide falls. In the depression between the coast range and the second range of hills artesian wells can be made, and these were used where none of the mountain streams were available. An English Company was working on a salt marsh by the aid of artesian water only, but it was generally considered that it would not be a success, as the amount of artesian water was after all only trifling compared with the area to be reclaimed. The universal opinion in Utah was that if they once succeeded in covering an alkali field with a crop of any kind, the victory was won. After the land was half cured, they generally covered it with a hardy grass, the most approved being red-top American grass. Beetroot was also said to grow well as an early crop; after that Indian corn and other crops by degrees. Tuberous crops grow well in the country, and the potatoes are said to be the best in the world. The last method I shall mention was that employed by Brother Fenton, an energetic Devonshire farmer. It happened to be impossible for him to get fresh water to wash the salt out of his fields, and he tried large quantities of manure, —20 to 50 tons per acre. Barn-yard manure was considered the best, and, as his great object was to keep the surface from the sun which drew up the salt, he also used litter to cover it. The first crops he covered the ground with were the red-top grass and oats, and he sowed his crops in September, so that the ground should be covered with vegetation when the alkali would be appearing. As soon as by this means he got his first crop of red Timothy grass, he found he had succeeded. Mr. Fenton complained that after partly curing one field, he ruined it by trenching and bringing up a saline subsoil. His idea was that the salt was a sort of perspiration of the earth and, therefore, mostly on the surface, and that by turning up the subsoil he would get a better soil. In India it is certainly the case that a short distance below the surface less *reh* is found. It may be different in a closed basin like that of Utah, where the subsoil also may become saturated with salt. Utah city is partly situated on bench at the base of the Wasatch hills adjoining the plains, and at first the farms surrounding it were made on the ground that was not saline. About one-fourth of the land under cultivation was salt, and three-fourths of this had been cured by sheer cultivation, much in the way I have described in the case of Mr. Fenton's farm. For the other fourth sluicing and irrigation had been available. The cultivation of saline soils is also carried out in other settlements. In most old settled countries, and especially in India, agriculturists are very conservative in following the practices of their forefathers. In America, where the population is composed of emigrants from all countries, every man brings the method used in his own, and all sorts of trials are made and the fittest survives. These are made in a new country under new circumstances, and people are not bound by traditional customs, but are anxious to try whatever succeeds in the hands of others, and also make experiments according to their own ideas. These may be crude, but still a vast number of experiments are made,—not isolated ones by a Government, but everywhere generally by the people themselves—and anything that is successful is hailed as a discovery. Some of the methods I have described as used in America may not alway be practicable in the plains in India. To run off the saline water requires a slope and lines of natural drainage that may not be available. It might be possible to run off the salt-impregnated water into absorption wells, thus returning the salt to its natural destination, the underground water. It is a law that a well will absorb as much water

without raising its level as it would give out without sensibly lowering it. This means has been used in some cases to get rid of liquid sewage, but was found to poison the wells. The plantation of trees is also proved to be a very efficient means of cure. The kikar is well known as capable of flourishing in such soils. They not only assist in moderating excessive evaporation by shade, but they also absorb and remove a certain amount of salt from the soil. As the alkali exists chiefly in the surface soil, and in much less amount at a small depth, trees may grow readily where annual crops could not. The latter have their rootlets only in the surface soil, and are poisoned by the excess of salt; while the roots of trees extend deeper into less saline ground; also plants not only consume portion of the salt, but they prevent its concentration on the surface. A most conclusive experiment made near the Western Jumna Canal by the Irrigation Department is reported by Colonel Fulton. A piece of utterly useless *reh* land, for which revenue was remitted, was taken up by the department and planted with kikar trees. These flourished and a very fine crop of *doob* grass, two feet high, came annually up under the trees, and the efflorescence disappeared. The villagers, seeing that the land was improved, and fearing it would be alienated by the new settlement, applied for the restoration of both trees and land, and carried their point in the courts of law. A few days after the restoration, the wood was sold to a wood merchant, and every tree cut down. At present the *doob* grass is all gone, and the soil is encrusted with salt. Such an experiment made among American farmers would have excited the keenest interest and given rise to numerous trials of the same.

The paper ends with an account of Dr. Brown's suggestions in regard to nitrate manures. It contains an immense amount of scientific information, concentrated in a small compass, and well deserves the attention of those who are interested in the agricultural development of India. We believe that Dr. Center has received the thanks of Government for his very able and interesting essay, which will shortly be published in the Records of the Indian Geological Survey.—*Civil and Military Gazette.*

WELLS AS A PROTECTION AGAINST FAMINE.

THERE can be no doubt that a very large sum has been well and liberally spent, and thousands of lives saved by the Indian Government during the famines of India, especially the last one. A few differences of opinion on the plans adopted were inseparable from so large an outlay over so vast an area, and among millions relieved. The important question still remains, how can such visitations, known to recur in cycles of seven or ten years, be best met and alleviated? To entirely prevent them in India, is simply impossible. They are visitations of Providence, on the failure of the periodical rains. In India, under the influence of a tropical sun, water will produce grain in almost pure sand. And no one therefore will probably question the oft-repeated assertion that irrigation (wherever practicable) should be extended to the utmost. It surely has been so to a very large extent. In three provinces in which I served (in Tinnevelly seven years, in Coimbatore eighteen years, in Trichinopoly three years), I know that under the care of intelligent engineer officers, almost every drop of available water for irrigation is utilized; in cut channels of seventy and ninety miles long, no waste water reached the sea, except at high floods; all river water is directed into watercourses, or into tanks. The rice crops were often finally saved by wells when the channels began to fail. But much lies behind the one word "practicable." Irrigation is only practicable in level tracts, bordering on perennial and unfailing rivers, chiefly from the S. W. monsoon. To cover India with a net-work of channels and series of tanks, all certain to dry up on the first failure of the monsoons, would only be a costly delusion. There are many provinces above the level of practicable irrigation, others with only small temporary rivers which are torrents in the rains, but dry beds at other times. Again there are soils unfit for irrigation where water, if supplied, either disappears as through a sponge (*e.g.*, the black cotton soils); or where the permeating water brings, to the surface, salts or other latent ingredients fatal to crops; (some such are found I believe in parts of the great Ganges Canal). I wish to advance no crude theories, but only a few practical facts gathered in forty years' residence and service in India, from careful observation and intimate association with the ryots.

The province of Coimbatore is a high-lying, dry district, incapable of much irrigation; with a rainfall under 20 inches per annum (on forty years' careful record), and therefore a good example of what is practicable, without irrigation, to alleviate a famine. In such a province (and doubtless there are many such in Bengal, Madras, and Bombay) what can be done to meet a drought? It is possible, as of old to buy up grain in the seven plentiful years and store it for the 7th or 10th of famine, Government selling it out at fair rates in the time of distress? It is worth consideration, but I fear it is impracticable. There are few Indian grains that will keep, except one or two kinds of millet (raggy, tenny, &c.). Rice and other grains rot, or are insect-eaten in three or four years; but millet, if preserved from the air, will keep twenty years and more. I do not agree with those who say that the Indian ryot refuses irrigation from stupidity or improvidence. The ryot, in my experience, though without science, is a shrewd observer of the nature of his own soils and of climate; and can get more out of his small farm of a few acres than most of his able European masters could do. He will use irrigation if it will pay him, he knows its value and often covets it, but he can often raise a cheaper and more saleable crop (than rice) by the rain from heaven for which he pays nothing. The water rates are often also too high; if lowered, water would oftener be bought by ryots and utilised in a dry season to assist a dry grain crop. Irrigation usually means rice only.

How then are a drought and a famine to be met? The only other means, and which I have long advocated is "well" cultivation: encourage wells, wherever possible, and there are a few provinces where they are not so. Wells can be and are sunk in all soils from 20 to 80ft. deep; costing from Rs. 50 to Rs. 1,000 each by the ryot himself for his own profit with no enhanced Government cess; but getting as he ought the full untaxed profit of his own labour and capital. This was formerly not so, but is I believe now conceded to the ryot throughout the Madras Presidency; if not, it ought to be. Government should advance small loans to the poorer ryots (without interest) for three or five years, to be repaid by instalments on the mortgage of their (saleable) lands. I advanced in Coimbatore in this way (under Government sanction), Rs. 50,000 and 5,000 new wells were dug by the ryots, and the whole amount lent was duly recovered, without a single failure, within the five years. Had I remained in the province, I should have repeated the process. During the last famine, I have reason to know the Coimbatore wells saved many a family from starvation and ruin. One failure of a monsoon dries up all tanks and channels not fed by a perennial river, but a well will stand one and even two such failures; it will still irrigate a portion of the land immediately round it; and save grain enough for the ryots' family, while the straw saves his cattle; with drinking water for both. Moreover the water raised and used for the fields near the well, percolates partly again into the well and is raised a second time for renewed use. Not so with a tank or channel; the water flows once over and off the field and is lost. The well too is the ryots' own property, and adds tenfold to the saleable value of his land, and is thus a safeguard and an advantage both to the ryot and the State; for if the ryot prospers, the State benefits and is sure of its rent.

In looking at Indian agriculture, we must not take an English view only, but look also at the peculiarities of the Indian soil and climate; the ryot knows them well, and acts accordingly, and with his apparently rude but sufficiently apt implements, he draws from the soil as much as any scientific European could; he knows the value of manure and loses none. Some people say, "the ryot should try deep ploughing:" I reply—" excellent in Europe; impracticable for the most part in India." You may as well try to plough deep a hard barn-floor, as a sun-baked Indian dry field, with small Indian cattle. It can't be done in any but the friable and light "black cotton soils" so called, which are porous and do not cake, but crack and open under a hot sun. Even then it can seldom be done; it would require four or five yoke of oxen at least to each plough; and the ordinary ryot has seldom more than one, or at most two yoke. Then "why not breed and use larger cattle?" Again I reply, "usually impracticable; there is no pasture fit for such; larger cattle could be bred in a few favoured localities and high table-lands like Mysore, not in the plains of India usually:" the plough may be improved, the cattle cannot. The Indian Government have tried many improvements. I had under me four fine thorough-bred stallions (of Government) to improve the breed of horses; several fine bulls; fifty merino rams. All had much care bestowed on them; the experiment looked well for a few years, and then failed; climate, soil, and pasture were against it; the progeny dwindled down to its original standard; the foals degenerated; the heifers the same; the lambs became hairy, and the old (woolly) merinos gradually died from the heat, and poor pasture. I am only giving facts. The experiments were begun by my predecessors, and carried on by myself for some years, earnestly and carefully.

No doubt Indian agriculture is much as it was 500 years ago; not from the ignorance or apathy of the ryot, but from the necessities of climate and soil. With a good soil and water much may be and is done, new crops, as flax, and others, can be, and are raised; but such are limited. A large province such as Coimbatore, 90 miles from E. to W. by 120 from N. to S. is a fair sample of many Indian districts, dry and of poor soil. I lived and moved in it for eighteen years, and, I hope, improved it somewhat; but not by unsuitable European machinery, nor deep ploughing, nor irrigation, nor teaching "ignorant ryots" what they knew already. I have in my own limited sphere urged "wells, wells," for many years, and I have yet to learn any better alternative, especially when it involves no State expenditure, beyond moderate, safe recoverable loans, the stimulating, and enabling the people to help themselves. I repeat, I see nothing equal to enlarged well cultivation, fostered by Government, to enable the ryot in a year of drought and consequent famine, to tide over the crisis for one and even two years. The loss to the State by small loans is simply the interest of the money for five years; the gain, the life and stability of the ryot, and ultimate advantage to the State itself, both interests being one. We shall no doubt have famines again, How can we best meet them, is worthy of much thought and inquiry, and of every practical suggestion.—M. C. S. in *Madras Mail.*

VILLAGE TANKS.

UNDER the title of "The Backwoods of Ceylon," in a recent number of the *Fortnightly Review*, the reader is told how "by engaging the natives on the side of work and activity, and by using and enforcing for that purpose the rules which their own immemorial customs have prescribed," the Government of Ceylon are solving the great problem of how to get the tanks of the country repaired, to a great extent, by the villagers themselves. This is of interest for India; and the more so since the people of the district,—the interior portion of the northern half of

Ceylon,—where the experiment is being made, are of the same race, with the same social institutions, as the people of India. Some centuries ago, when Anuradhapura was a centre of attraction to Buddhists, the whole plain was a highly cultivated country with its villages, tanks, and paddy-fields. Now the villages are in ruins, the tanks out of repairs, and the paddy-fields are covered with a dense impenetrable jungle. And all this is due to neglect of the system of irrigation which the rulers of a long past age had so wisely planned and carefully executed. When Sir Hercules Robinson was Governor, he saw that the ancient system of settling purely local disputes by the elders of the villages was in great danger of disappearing before the encroachments of the criminal courts. As a measure of judicial reform he resuscitated the institution which governed the village communities, by passing what is known as the "Village Communities Ordinance." When Sir W. Gregory introduced a scheme for making each shareholder in a village responsible for doing a proportionate share of the work of restoring his own village tank, the revival of the old institution of the country was found to be of the greatest value. According to the rules now in force, every shareholder in a village is obliged to give annually such labour, not exceeding that of an able-bodied adult for 30 days, as the Government agent may declare necessary for the repair of the village tank. A shareholder may at a certain rate commute his labour for money, but in order to do away as far as possible with cash transactions this is discouraged. In consideration of the villagers doing all the earth-work connected with their tank, Government supplied an iron sluice fixed in solid masonry. This scheme was commenced in 1874. At the end of 1878, or in four years, 856 tanks had been more or less repaired by the villagers, and Government had supplied sluices to 117. The estimated value of the work done by the villagers, was Rs. 3,90,000, while the cost to the Government for sluices was Rs. 1,30,000. There was some difficulty with the first few villages to make their inhabitants understand that they must perform their obligations; but a little judicious severity soon brought them round, and now they look with pride at the amount of work they have done. A calculation having been made as to the amount of earth in cubic feet which would fairly represent the number of days' work to be done, the ground is marked out for each shareholder. So long as he digs out the pit to its proper size, and places the earth on the bund of the tank before a certain given date, the times and seasons for working rest with the shareholder. The general supervision of this work can safely be left to the village community, who are keenly jealous to see that each individual does his allotted share of the task.

The words "forced labour" have an ugly sound, and in one sense there can be no doubt that Sir W. Gregory's scheme is nothing more than forced labour and a return *with improvements* to the old system in force under the native *raj*. But if this system is found to work easily in Ceylon, why should it not be introduced in India? In teaching the people of this country the great blessing of individual liberty, we have too long forgotten to instil into their minds the principle that the individual owes a duty to the community at large. In no case does the duty come out more strongly than in the repair of the village tank. Personal labour to be given, within certain limits at his own convenience, is a form of public duty well suited to the purse and character of the people, and one in which the individual can best fulfil his obligations. While putting the individual to no expense, it enables the Government to spend the public moneys on that kind of work which the villagers could not themselves carry out. The maintenance of the village tank is a matter in which all the villagers as a body are interested. The work of an individual, however willingly performed, is of itself inadequate. All must combine and each perform his own proper share. But the petty jealousies among the villagers in the absence of an acknowleged head prevent combination even for the performance of a common useful object. The old village institutions have gone down before British administration. There is no one who can command, no one whom all will obey. The Ceylon Government, by officially recognizing the institutions which formerly governed the village community, have given to the elders of the village a position which all cheerfully acknowledge, all obey; and has furnished itself with a valuable agency for carrying out local public works. What has been a possibility for the Ceylon Government ought not to be an impossibility for the Indian Government.—*Pioneer.*

THE OPIUM DUTY.

THE *Bombay Gazette* tries to prove in the following extract that the Government loses about two crores of rupees of opium duty every year:—

With respect to the question of the relative amounts derived from the Bengal monopoly, and the Bombay pass duty, we will, to make the matter clearer, give a few figures which leave no doubt that we have given a most profitable monopoly to the Native States and populations of Central India. A chest of Malwa opium of the usual consistency, 95 per cent., is equal to $1\frac{1}{4}$ chest of Behar, which is of 75 per cent. consistency only. Now a chest of Behar at last auction realized Rs. 1,406, the cost of which to Government, with interest on capital, is Rs. 380, leaving a clear profit of Rs. 1,026; but as 1 chest of Malwa is equal to $1\frac{1}{4}$ chests of Behar, if the profit on the latter be Rs. 1,026, it ought to be Rs. 1,282 on the former. But the pass duty being only Rs. 700, Government clearly suffer a loss of nearly Rs. 600 a chest on Malwa. We have seen that our N.-W. P. ryot voluntarily cultivates the opium for Government at less than Rs. 380 a chest; the equivalent for a chest on Malwa to the Central India cultivator is Rs. 475, or very nearly the figure we put down, in our last article, as the fair share in an ordinary or average year. That will still leave our Government out of pocket to this extent of Rs. 500 a chest in the collection of revenue on Malwa opium. And taking the average export of that drug, at say 40,000 chests a year, the loss to our finances comes to two crores of rupees. This is not a sum to be lightly thrown away during these times of normal deficits, as we believe and we hope we have made it sufficiently clear that this loss is simply owing to the want of proper skill in arranging the incidence of the opium taxation. Can it be fair and just, that while we exact the uttermost pie from our own heavily taxed ryot, we should be so lavishly generous to the untaxed foreign ryot and the protected native prince, for whom we have actually created a monopoly by prohibiting the poppy culture in our districts? It is to be trusted that our remarks may be able to rouse the attention of Government in the Financial Department, and some means may be devised to secure to our revenues an equitable share of the enormous amounts which our own policy with respect to China has provided for the Central India States and their population. It is a notorious fact that the cultivators and dealers have waxed so rich of late, that the former are able in most instances to hold the valuable product of their fields for months and months without any assistance from the sowkar so necessary to ryots in our territories; and the dealers are now actually holding back a large proportion of last year's crop, and delaying the one for this year, in the vain hope of frightening our Government into lowering the pass duty, and that too with heavy stocks and the fact of a more than average crop for the year, staring them in the face. We must confess, however, that of late the figures for Malwa opium revenue have been small, and may have raised anxieties as to the future; but the Central India Agency can easily ascertain the amount of stock held over from last year's crop and the quantity of new crop juice already warehoused at Oojein and Indore. We are confident that the figures will largely exceed those of last year. Only a few timely showers or an intimation from Government that, far from contemplating a reduction they were resolved to raise the pass duty, say from September, when the new crop is all manufactured, will set free the usual stream of shipments from Bombay.

BAMIEH COTTON.

A CORRESPONDENT who signs himself "Observer," sends us (*Bangalore Spectator*) the following notes about Bamieh cotton, which we think will be interesting to our readers:—

During the last three years or so there have been several articles in the *Indian Agriculturist* on the cultivation of the "Bamieh cotton," the subject being so strange, as to make it almost incomprehensible. From all known precedents, it would not be safe to launch out at first on an extensive scale, as experiments in India to the present date have not been satisfactory, from a variety of causes. What are Government and our Agricultural and Horticultural Societies doing? But as in many other projects, so in this, the interloper must begin and go on spending time and money till he succeeds, and then pay tribute to his paternal Government. The only way at arriving at satisfactory result would be an experiment in a small way in the kitchen garden, where the master can be continually present, either to do everything himself or supervise all that is to be done.

This prodigy may be of the *Mule type*, unable to reproduce itself, or if able to do so, perhaps, only in a meagre way, for want of a revivifying power, which I will state further on, Now look at the cocoons spun by the silkworm, of which the varieties are white and yellow. When these are put by for propagation, the white and yellow are always carefully put away separately, but it often happens, that some get mixed, and the result is, that in the next batch of cocoons there is a third variety, *i.e.*, of a very light green kind, and these have invariably been quite superior in every way to either the white or the yellow from which they sprung. I have known trials to be made for several years to get the moths of this kind to give this variety; but all to no purpose, for instead of getting this light green, there would be a mixture of yellow and pure white. For many years, it was supposed that one vaccinating operation was sufficient for a life time, while now it is only considered safe for seven years at most.

It would be well for those who have time and the inclination, to make the trial in two distinct ways: *1st*, by sowing some cotton together on one side, *2nd*, by sowing the Bamieh quite apart by itself. If the former turns out a success, and the latter a failure, then the seeds of Bamieh in its vegetable or *original* state must be sown afresh, year after year, between rows of cotton trees, and for this purpose preference may be given to the Parnambuca cotton plant, for two reasons:—*First*—this plant grows on for years, and consequently will save all the trouble and expense of raising fresh plants from year to year. *Secondly*—the pods of the Parnambuca plants are larger than those of any other plant, while its staple is the largest and silkiest of all others. It is from the cotton of this plant that the sacred thread of the "twice born" and Rajpoots is made. It is to be had in gardens. It would, however, be advisable to try with a variety of cotton plants, so as to be able to prove which kind would be the most profitable, and if getting the most profitable crop comes from the Bamieh direct, there will with it be the value of the fibre of that plant.

I have no doubt that there are many who would be glad to make a trial on a small scale, and if anything herein stated will in any way be of use I shall be quite satisfied.

ASIATIC CAOUTCHOUC.

THE credit of first bringing to the notice of Europeans the existence of Caoutchouc in the East, seems to belong to Mr. James Howison, a Surgeon in Prince of Wales Island. In his paper on "The Elastic Gum Vine" of that island, published in the 'Asiatic Researches,' 1798, he says that the general way of obtaining the gum, was by cutting the plant into lengths of about two feet. By means of wax moulds he made himself gloves, boats, waterproof garments, and other articles. This plant was named by Dr. Roxburgh, "*Urceola Elastica.*" The next discovery was in 1810, by Dr. Roxburgh himself, who receiving from Silheb a turong or basket filled with honey, as a present, found that the lining of the turong possessed greater interest to him than the honey, being of Caoutchouc. He named the tree producing it "*Ficus Elastica,*" familiar to us as a window and greenhouse ornament in England.

I shall first speak of the caoutchouc produced in India, and from the Malayan Archipelago from a species of "*Ficus.*"

Assam or Sylhet caoutchouc, as it is sometimes termed, is the only kind obtained from India, and is the produce of the "*Ficus Elastica*" of Roxburgh, known in Bengal as "Kusnir" or "Kasmeer."

The trees are cut with a knife, and the milk is received in holes prepared in the ground, or leaves folded up in a funnel shape. About 50 ounces of milk is the average yield of a tree, giving about 15 ounces of dry caoutchouc. To prepare the "loaf" kind, the milk is poured into boiling water, and stirred till it acquires some degree of firmness, and then dried. The small "ball" kind consists of strings of caoutchouc, which has been allowed to dry on the tree. Assam caoutchouc, either in the form of large blocks or separate balls, is shipped from Calcutta in baskets made of split rattans, and generally covered with a "gunny" bag, such baskets weighing about 3 cwt. each. This caoutchouc, and indeed all caoutchouc prepared from a species of "*Ficus,*" has a peculiar mattled appearance; in this variety the colour of the various agglunated juices ranges from cream or flesh to that of pink colour, verging into red, and with a glossy surface. Its good qualities, however, are much injured by gross adulteration with sand and other impurities. In the Malayan Archipelago, large quantities of caoutchouc are produced and exported to this country.

AFRICAN CAOUTCHOUC.

MADAGASCAR, termed also "Mauritius" caoutchouc, though not known so long in England as in France, has quietly risen into favour. It is the produce of two or three species of "Vahea," found also in the Comoro Islands, *viz.*, "V. Gummifera," Lamarck (called Vaughnia by the natives). "V. Madagascariensis," Bojer, called Voua, and "V. Camoriensis," Bojer, a beautiful shrub, 10 feet high, with white, sweet scented flowers and fruit of the same shape and colour of an orange. In Madagascar the natives prepare the caoutchouc by means of salt water or artificial heat. It is rather more pinky in colour, but otherwise much resembles that of Borneo.

West Coast.—One of the principal plants producing this caoutchouc has been identified by Dr. Welwitsch, the Portuguese botanical explorer, as the "Landalphia owariensis" of Palicat de Beauvais. It is known to the natives as "Lecongue" or "Sicomgue," and is described by him as a large climbing plant, 4 to 6 inches in diameter at a height of 2 or 3 ft. from the ground. From this point it divides into several long thin branches, which are sub-divided, climbing along the stems and larger branches of neighbouring trees, to which they fix themselves very tenaciously by spiral tendrils formed out of the indurated flower stalks after the ripe fruit has fallen off. The fruit is like an orange, with a hard reddish-brown shell, containing sweetish aciduous pulp eaten by the natives.

In the case of such a very useful and highly necessary article as caoutchouc, the question naturally arises, how can we secure lasting supplies at a sufficiently cheap price, as it is a well-established "axiom" that we cannot long depend on the spontaneous products of the forests, or rely on the caprices of native collectors, and that recourse must be had, sooner or later, to cultivation. I have strongly urged this necessity and will mention some of my reasons for so doing. I first shewed the desirability of cultivating the "*Ficus Elastica*" in India on as large a scale as possible, and also how the caoutchouc should be collected and prepared. The mode of tapping as generally practised is exceedingly hurtful to the trees, and I have recommended the use of a kind of "tapping" knife which should only cut through the bark and save the wood from injury. Trees so tapped or bled should be allowed a period of rest of from two to three years. Proper metallic vessels should be provided to collect the milk so as to prevent contamination with clay, &c.

As to the preparation of caoutchouc, several methods are resorted to which may be thus classified:—

"Group" I. Coalescence brought about by heat. Examples:

1	Artificial heat	(dry)	Pará, Madagascar.
2	"	(hot water)	Assam.
3	Natural heat		Assam, Ceara.

"Group" II. Coalescence brought about by the addition of various substances:—

4	Alum		Pará.
5	Liq ammoniæ fort		Pará African (best kinds)
6	Anacid?	(acetic acid)	Pará.
7	Certain plants		Nicaragua.
8	Fresh water		Borneo, Madagascar.
9	Salt water.		"
10	Sulphur		Pará.

Of all these various methods that of dry artificial heat seems to be much the best, though aqueous preparation is also good, if means be taken to dry caoutchouc by adequate pressure. The milk should be strained with a sieve before submitted to coagulation, to free it from accidental admixture of bark, &c. It should also be prepared in the form of thin cakes, to reduce the possibility of adulteration to a minimum.

Thus, two of the chief desiderata, "purity and dryness," would be secured. I have endeavoured to show the great desirability of the acclimatisation and cultivation of the Heveas yielding respectively Pará Central American, Madagascar, African, and Borneo caoutchoucs, Castilloas, the Vaheas, and Landolphias and the Urceola.

The Para caoutchouc is undoubtedly the finest known, and, where the question of price does not interfere, is used for the most valuable articles. Madagascar caoutchouc comes next to that of Pará, and I mentioned that all of these trees would be improved by careful cultivation, and that the caoutchouc from them would be held in high estimation. Larger quantities of good caoutchouc at a cheaper rate is much wanted, and if supplied, would lead to corresponding increase of activity in its industrial applications.

Crude India-rubber juice, when first obtained from the tree, has the appearance of a creamy substance, like cow milk, and has a smell of cheese or putrescent milk.

The following are the prices paid per lb. for best description only.

	s.	d.
Pará	2.	11
Ceará	2.	0
Carthagena...	2.	1
Guayaquil (pressed)	2.	1
African	1.	11
Honduras	1.	11¼
Mexican	1.	10½

Allowing all the varieties to be "equally pure," their relative value may be taken in the following order:—

Pará, Madagascar, Carthagena, Ceara, West India (sheet), Guayaquil (pressed), Singapore, Assam, Penang, Guayaquil (common), African, Borneo, and Guatemala.

ARTESIAN WELLS.

MR. W. KING, of the Geological Survey, in an "additional note on the Artesian Wells at Pondicherry," remarks:—"An important fact was brought to my notice by his Grace the Duke of Buckingham in connection with the tidal observations made at Madras by Colonel Baird, which shows that there is very free percolation of fresh water into the sea on the coast there. It appears that a well or cylinder was sunk in the vicinity of the harbour works for a tidal gauge, and it was found that the water in this well became fresh in a very short space of time. This indicates a head and large supply of water which should be struck by borings of no great depth. It may be that a stratum of this kind has been tapped by all the wells, except that of the Ville Noire and in the neighbourhood of Pondicherry, the few tubes put down having offered a freer exit than that existing, not only on the sea face, but also in the beds of the rivers near the coast. This observation at Madras, implies that the flow of water shows itself at a very shallow depth, but the free percolation must be deeper than this under the Madras plains for it is well known that at the ordinary depth to which open wells are made here, there is not free communication of their waters. For instance, in many compounds, wells have been dug at various spots, only some of which contain fresh waters. A case in point is that of Mr. Franck's compound on the Mount-road, an area of about 3 or 4 acres, in which, as far as I remember, 5 wells were dug, most of which gave brackish water,—so here in this small space and at a very shallow depth are seams of permeable strata which can hardly be in free communication with each other."

A NEW PLOUGH

WE believe that Mr. T. T. Leonard, who possesses a very flourishing farm at Kristnarajpuram, some four miles from Bangalore near the railway line, recently imported a new pattern plough from Cawnpore which has attracted the attention of the local Government, owing to the advantages it has over other ploughs which have been introduced into the province. In the first place, it is so light, that a ryot can carry it on his shoulder, and any ordinary pair of cattle can drag it. The great difficulty with the English plough has been that it required very superior cattle to drag it, and, of course, poor ryots could not afford to launch in to the expense that it would entail. Then again, the Cawnpore plough can be made to turn up earth to the depth of twelve inches; it can be repaired by any village blacksmith when damaged, and it only costs four rupees, while the average English plough costs thirty! We understand that Mr. Gordon has ordered some of these ploughs from Cawnpore, and intends to explain their advantages to the ryots, and to induce them to invest in them, if possible. The idea is a good one, and we hope it will succeed. Mr. Leonard must be complimented highly on the service he has rendered in the cause of local agricultural reform by his introduction of the plough.—*Bangalore Examiner.*

VEGETABLE TALLOW.

THE *Englishman* says:—There is an opportunity in Borneo for any one desirous of opening out a new industry in these hard times of slack trade and over-competition. In that island among other productions, there grows a tree which the natives call *Tangakwang Tenggal*, which, no doubt, must be a very euphonious name if pronounced with the true accent. The speciality of the tree is that it yields fruit out of which a very excellent description of tallow can be and is obtained. The wood is also extensively sought after by the Dyaks for prahu-building

purposes, but the tallow-yielding fruit is its distinguishing and most attractive point. The tallow is obtained as follows—The fruit is allowed to remain on the tree until it ripens and falls off. It is then dried in the sun, by which process it grows brittle, and the outer skin can be peeled off. It is next put in a bamboo basket and steamed over boiling water until it becomes soft, and looks much like dough. It is now squeezed in a cloth and the oil exudes and is caught in vessels and allowed to cool, when it presents very much the appearance of wax. There is already some trade in this article to Singapore, amounting to several thousands of piculs, the greater part of which is, shipped to England to be used as grease for machinery. There is however, the possibility of largely developing the trade by proper means, and with every prospect of very substantial success. No European has as yet embarked as a manufacturer of the tallow. That portion of the business is left wholly in the hands of the Dyak tribes of Borneo, who, as might be expected, use very primitive means, indeed, for extracting the oil. There is therefore a new opening for European energy and skill backed by all the latest improvement."

We may add that the Straits Government are sending sample of these tallow seeds and a bottle of vegetable tallow to the Melbourne Exhibition.

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The usual Monthly General Meeting was held on Thursday, the 26th August 1880.

W. H. Cogswell, Esq., V. P., *in the Chair.*

The proceedings of the last meeting were read and confirmed.

The following were elected Members :—

Mrs. A. J. Hughes, Messrs. W. Mackenzie, Newton E. Jennings, and the Secretary of the Patna Municipality.

The names of the following were submitted for membership :—

Rai Jaikissen, Honorary Magistrate of Patna,—proposed by Baboo P. C. Mittra, seconded by Mr. S. H. Robinson.

Captain W. A. J. Wallace, R E., Saidpore,—proposed by Mr. H. J. Leitch, seconded by Mr. R. A. Lyall.

Charles Ryves, Esq., Deanstone Tea Estate, Urngala, Ceylon,—proposed by Mr. J. W. O'Keefe, seconded by Mr. J. E. MacLachlan.

A. B. Holmes, Esq., Blackburn Tea Estate, Debrooghur,—proposed by Mr. W. H. Cogswell, seconded by Mr. W. Stalkartt.

Rejoined—C. T. Castle, Esq., District Superintendent of Police Budaon, and Lieut.-Col. H. R Wintel, commanding at Futtehgurh.

Contributions.

1. Memoirs of the Geological Survey of India.. *Palæontologia Indica*. Ser. XIV. From the Superintendent.

2. Journal of the Bombay Branch of the Royal Asiatic Society, No. 37, Vol XIV. From the Society.

3. Transactions of the Asiatic Society of Japan. Vol. 8, Part 2. From the Society.

4. The *Indian Forester* for July 1880. From the Editor.

5. Memoirs of the Boston Society of Natural History, Vol 3 Part 1, No. 3. Proceedings Vol. 20, Parts 2 and 3, and Occasional Papers, Vol. 3. From the Society.

6. A number of Mahogany seedlings. From the Superintendent, Royal Botanic Garden, Howrah.

7. Seeds and plants from the Nicobars. From E. H. Man, Esq.

8. Seed of the Wild Vine of California. From John Martin, Esq.

9. A small quantity of acclimatized Tea seed from Bettiah. From C. F. Carleton, Esq.

Seed Potatoes from Melbourne.

The Secretary intimated that he was unable to carry out fully the resolution of the last Meeting in respect to the potatoes received from Melbourne, in consequence of its being too early in the season for sowing at Darjeeling and other hill stations. He had sent out two or three boxes to other localities with the remote chance of succeeding. Messrs. Anderson, Wright & Co., had again kindly promised their assistance towards obtaining another supply in the cold season.

Ploughs.

Submitted a letter from the Secretary in charge of the Experimental Farm at Cawnpore, intimating that the plough reported on at the last Meeting was Mr. Crawley's private plough, and not that employed at the Model Farm.

Submitted also the following letter from Dr. Macgregor, Superintendent of the Benares Central Prison:—

I am in receipt of the report of your Sub-Committee on the Benares Jail Plough, and while grateful to the Committee for the trouble they have taken in the matter, I am unable to accept their verdict as satisfactory for the following reasons :—

(1.) This plough alone has been used in the Jail Farm for over a year, and during that time over 200 acres of soil has been turned over.

(2.) During the ploughing season there are from three to six in daily use in every kind of soil and with every variety of crop. That the work is efficiently done, no one who sees it can have any doubt about.

(3.) This plough makes ridges or drills for potatoes, carrots, turnips, cane, cotton, &c., &c., which the native plough cannot do.

From the above it is not unreasonable to suppose that to the inexperience of the ploughman employed by your Committee, the failure of this and the Cawnpore ploughs are due. It requires some experience to properly adjust the length of the full rope, if too long, the nose of the share buries itself in the ground. Mr. Martin's plough being on the native system was more easily managed by an inexperienced ploughman. If you remember, I volunteered to send a properly trained ploughman to work it, and if I had done so the plough could not possibly have ailed. Here it has long passed the stage of experiment and become part of the routine work of the Farm. If your Committee consent to re-open the trial, I shall send a man at my own expense to work the plough, only stipulating that he should work the bullocks for a day or two's practice beforehand, for bullocks require training as well as the ploughman. I am aware of the prestige attaching to the report of your Committee and would do all in my power to place the plough in a more favorable light, because I know what it can do.

Resolved, that as the piece of ground in the Society's Garden on which the experiment was made, is now utilized, and no other piece of ground is available, the Meeting regret that they are unable to re-open the trial

Crocodile Oil.

Submitted the following letter from the Secretary of the Eglinton Chemical Company, "Limited," of Glasgow, to the address of Dr. Kany Lall Dey Bahadoor :—

We observed some time ago some reference in a London newspaper to an examination which you had made of Crocodile Oil, and if we remember rightly, the name of Mr. Purcell of Agra was referred to in the same communication.

As we are going into a new process for manufacturing leather, in which process such an oil would be invaluable to us, we shall be obliged, if you will kindly say, from whom we can procure a sample of it, and at what sort of price it could be supplied. If, at the same time, you can send us a small sample, we shall be happy to pay the expense of same.

The Secretary reminded Members that Mr. Purcell's letter and Dr. Dey's report on this oil appeared in the monthly Proceedings for February 1879. He had lost no time, on receipt of the above letter, in addressing Mr. Purcell, but the letter was returned a short time ago, the addressee not being at Agra.

Agreed, that the letter be published in this day's, Proceedings in the hope that it may attract Mr. Purcell's attention.

Supposed value of the Juice of Euphorbia as a protection for Iron Work.

The Secretary brought to the notice of Members a letter from Col. W. M. Lees, which was inserted in the Proceedings of December last, introducing a cutting from the *Times* on the above subject. He (the Secretary) had addressed the Superintendent of the Botanic Garden of Cape Town on the subject, and had received the following letter from Mr. McGibbon on the subject :—

Since receipt of your letter of January last, I have been endeavouring to obtain more full information on the uses of Euphorbia Juice than I possess, but I am sorry to say, without success.

Euphorbia sap is not used in any form at the Cape nor is it an article of export. I have consulted the Customs Returns to that effect. In the neighbouring colony of Natal a patent was taken out, some years ago, for the use of Euphorbia sap made into a form of paint for use on ship's bottoms, iron and wood, and marine structures generally. I have not learned that it is used in Natal for those purposes, nor do I find any of the sap is exported. I am told that the preparation of Euphorbia juice is worthless as a preventative against the attacks of *animal* life on wood or iron in water.

The species of succulent Euphorbia are very numerous at the Cape. The largest growing Cape sp. is E. grandidens. It reaches a height of 20 feet with numerous fleshy branches irregularly arranged round a straight stem. It is very abundant in the Eastern districts of this colony. It bleeds freely and copiously.

Another sp. found more to the Eastward and in Natal is E. quinata (a bad name of no authority I fear). This is the largest growing succulent Euphorbi I am acquainted with, exceeding in height E. grandidens, and larger in circumference than that sp. A good specimen of E. quinata (?) is a handsome object, although of so singular aspect. The quantity of juice yielded by this tree is very plentiful. From this and the preceding sp. the sap was taken, I believe, for experiment. I would have much pleasure in sending you a few young plants or a lot of cuttings of both or of other Cape species of succulent Euphorbiaceæ, if you desire to have them.

Apologising for the delay in replying in reference to the above matter, I venture to add a request for some seeds, as much as can be conveniently spared, of Euchlæna luxurians. This plant succeeds fairly in certain situations, but it does not seed freely (as yet) with us. It is desirable to distribute seeds of the plant to our farmers. [A large quantity has been sent.]

Rheea Fibre.

The next paper submitted was a letter from Mr. T. Sandys, dated 3rd August, to the Magistrate of Bhaugulpore, on the subject of Rheea Fibre, which is forwarded, together with a piece of the Rheea fibre tape therein alluded to by order of the Government of Bengal, in continuation of the papers inserted in the proceedings of last month.

"In reply to Messrs. Burrows, Thomson, and Mylne's No. 2,188, dated Boheea, 30th June last, addressed to the Secretary to the Government of Bengal, General and Revenue Department, copy of which I am favored with under your Office Memo. No. 234 G. of yesterday's date, I beg to state that I know nothing of the Dhunook party, now said to have removed to Synthia, and whom perhaps you will be able to discover by making inquiry in that quarter.

"2. For more than sixteen years past, I have kept up a small cultivation of Rheea for experimental purposes only. Altogether I have followed out above a dozen experiments eventually discarding them all for one. During this long period, the various processes have been generally made no secret of, though there are portions I have kept in my own hands. They have been manipulated by various work-people, and are known to many. Plants may or may not have been surreptitiously obtained from my cultivation, as I took no particular precaution in this respect.

"3. I began with about 100 cuttings obtained variously from Chowringhee, Purneah, Dinagepore, and Rungpore. Eventually there being no particular difference in the outturn of these plants, they all get mixed up together.

"4. I have met with great reverses in the cultivation, the difficulties of which I regard as secondary, if not equal, to those of the extraction of the fibre. Nothing but the highest state of garden cultivation will answer. Will this pay? I think it will, provided that an economic organised system is pursued from the planting of the cutting until the fibre is woven into cloth, not otherwise. I cannot speak positively on this point, as it has not been worth my while to try it as yet on a proper scale. I have confined myself mostly to hand-work, though machinery may be largely employed at various stages. Life spared, I may follow it up two years hence when more at liberty. In the meantime I have been watching for the discovery of any better process than my own; satisfied on this point, I am ready to reject my own.

"5. Rhees, from the character of the plant, must be grown on high lands in contra-distinction to submerged lands. Hence, as a rule, high lands will always be of a poorer description than low lands, whilst it is always on the latter that white ants prevail the most. I purposely selected some high calcareous land abounding in kunkur to see what should be the outcome of a poor soil. The first two to three years the plant succeeded pretty well, but after this period the white ants seem to have discovered themselves stronger for the first time. After harvest cuttings they attacked the woody portion of the stem thus left exposed and burrowed downwards inside the roots, completely honeycombing them of their pith, leaving nothing but the bark untouched. They eventually attacked all weaker plants of all ages. I persevered several years, sometimes losing two-thirds of my crops, until wearied out, I removed the remains into a well-manured plot in the garden, where they at once recovered themselves, became healthy plants and have given good produce.

"6. Whenever convenient to you I shall have much pleasure in showing you this plot, and present you with a ripe plant, entire, which you can send down to Dr. King by the night train, and it will reach him the next morning, quite equal to retransplanting and watching it will be more complete than a supply of leaves only. Annexed is a photograph of one of my oldest plants which escaped the white ants' outrage. I did not observe that the calcareous soil was particularly detrimental to the plant. Its roots pierced to considerable depths, and I have actually found roots growing through crevices in the kunkur nodules themselves.

"7. Through the Imperial Government I offered to make my processes known at the late Saharunpore trial, and I sent on three samples of its cloth roughly woven, still retained, though that is immaterial, as my later process is an improvement. The Committee did not accept my offer. I could not compete under the conditions of the advertisement. My processes are not immediate, but require time, though it does not necessarily follow that they must therefore be rejected as expensive. My many years' experience goes to show that any violent rapid extraction of the fibre is injurious to its strength. The fibre can be brought out white and silky in its green state, in a few hours, but very much entangled and ruined.

"8. Enclosed are two samples of half an inch. Tape, according to my latest process, spun and woven by a common village-weaver with his rude implements. I shall be very glad to communicate my process to any one who will put me in possession of a better one."

Applications for Seeds and Publications.

Letters were read—

From the Director, Department of Agriculture, N.-W. P., requesting the aid of the Society in procuring a quantity of the "wheat rice" from America, which is referred to in following extract from the *Pall Mall Gazette*.

"A new sort of wheat, which is said to have been discovered in Arkansas about two years since, is at present attracting the attention of farmers in the United States. It is called wheat rice, and is supposed to have been originally brought to America by emigrants from the south of Russia. The grain is said to be well rounded and full, rather smaller than that of corn, yielding a fine white flour, which is more nutritious than either maize, oats, or rye, and forms an especially good food for every kind of cattle. The stalk of the plant is described as being tall, stiff, and plentiful. One of the peculiar qualities of the new cereal, and one which makes it particularly suitable to certain soils, is that it will live and thrive in districts where other kinds of corn would die on account of the dryness of the land. It remains unaffected by a drought of eight months. Its hardiness is likewise shown by the fact that it resists the attacks of almost every sort of insect, and the cost of cultivation is much less than that of wheat, maize, or rye. On analysis, the new corn has been found to contain 4 per cent. more starch and 3 per cent. more oily matter than wheat, but, on the other hand, it possesses 2 per cent. less nutritive matter, and 5 per cent. less water."

From the Secretary, Local Fund, Kohat, to the same effect.

The Secretary intimated that steps had been taken towards meeting these applications.

From Secretary, Public Garden, Sumbulpore, applies for seeds of various kinds of the *Eucalypti*. Complied with.

From L. A. Bernays, Esq., V. P., Queensland Acclimatisation Society, acknowledging receipt of certain recent publications of the Society and asks for back numbers of Journal, Vols. 1 to 4, new series, to complete the set, "as your Proceedings and Journals contain so large an amount of most valuable matter."

It was agreed, on the recommendation of the Council, to present these back numbers to the Society in return for the many useful plants and seeds which Mr. Bernays has contributed towards this Society's Garden.

From Messrs. Thomson and Mylne of Behera, forwarding some printed copies, giving detailed statements of the advantages derived from the use of their sugarcane crushing mill, as proved by the figures of comparative costs given.

MINERALOGY.

A COPPER Hindu idol, representing a woman with four arms, has recently been unearthed near Orenburg. Archæologists believe it to have been the prize, several centuries ago, of some of the Mongols who invaded India, and to have been conveyed in the course of their nomad wandering to the spot, where it was discovered in the Orenburg district.

London speculators in gold mining shares may perhaps soon find a sphere of activity nearer home than the Wynaad. We read in a home paper that there is a prospect of operations being resumed at the Kildonan gold diggings, Sutherlandshire. A German gentleman has lately been testing the gold-producing properties of quartz taken from several points. The results are reported to be very promising. A chemical process will be adopted for separating the gold from the quartz. Persons long resident in Australia state that they are struck with the resemblance of the geological features of Kildonan to those of the Australian gold fields.

THE WYNAAD GOLD FIELD.

[Mr. H. A. Severn, who is far-and-away the highest authority, on gold mining now in India, and, indeed, one of the first authorities on gold mining in the world, has sent us [*Times of India*] an admirable letter, showing the mischief that will be wrought if anything like a gold mania is forced upon the Indian public. He is, however, terribly outspoken, and though we should like to publish every word he writes, we are constrained to acknowledge that such publication might be inexpedient as well as unpalatable at the present moment. We shall therefore, confine ourselves to a few salient, if impersonal excerpts.]

TO THE EDITOR

* * * * * * *

Sir,—There is a vast difference between such reports as these and reports founded on a real practical basis. The former are not worth the paper on which they are written. The preparation of the latter is among the most difficult and delicate of scientific tasks.

* * * * * * *

There are men down here pretending to possess an acquaintance with gold mining and crushing, who to my own knowledge have drawn up lengthy reports after having washed off one or two dishes of earth, and receive for the said reports large sums of money. Such proceedings are wholly detrimental to the development of this district, and are a simple and ready means for blinding the public, for pecuniary ends. During an experience of twenty-seven years I have been constantly on gold work, followed it with scientific care, by day and night, into its many and varied ramifications, seen it in every form, above ground and beneath it, almost pure, and associated with silver, antimony, copper, iron, &c.; have put up crushing mills, burnt tailings, and have treated specially many thousand tons of quartz. In view of this lengthened experience on this special kind of work, and aided as I have been all through life by strong proclivities for physical science, I naturally feel a deep regret that persons should be tempted to draw up reports having little or no practical acquaintance with the subject, but only with a view of misleading the public mind. My intimate friend, Mr. Ruskin, said well when he called Mr. Whistler "a cockscomb and an impostor" for flinging a pot of paint at the public and calling it a picture. Fortunately Whistler as an artist is defunct. That all impostors, though they may be "*artists*" in one or several professions, may become extinct sooner or later, must be the earnest wish of all real practical men. My earnest endeavour during all these years has been to promote the application of science to practical ends. In the colony of Victoria, in New South Wales, in Queensland, in South Australia, in New Zealand, and in England, these facts are well known, and H. E. the Governor of Bombay will, I feel sure, bear his testimony to my statements should it be necessary.

* * * * * * *

Yours, &c.,

Davallah. H. A. Severn.

INDIAN COAL.

CAN nothing be done to improve the demand for Indian coal? A large and important industry seems almost starved by the limited demand which exists for the output of the Indian mines. During 1878, the total output was 1,015,210 tons, as against an average of 817,602 tons for the three preceding years. At the same time India continues to import the article largely, for the consumption of coal is on the increase. During the three years ending 31st March 1879, the average quantity imported was 522,755 tons, valued at Rs. 92,10,451, a valuation equal to Rs. 17-10 per ton. There is this peculiarity about the coal industry, that the quality of the coal interferes with its use in a large number of instances, and no amount of commercial enterprise can remedy this. In other industries one can improve matters by giving closer attention to the modes of production, but with coal no amount of care can improve the raw material. If one could by any means reach an improved quality of coal, or a quality in any way equal to that of the English mines, not an ounce would ever be imported; but this seems out of the question.

Indian coal is cheaper per ton than English, and for many purposes does quite as well; but when space is a factor in the calculation, as on board of steamers, the Indian coal is heavily handicapped, in spite of its relatively lower price. One ton of English may be as serviceable as one-and-a-half ton of Indian coal, while in many cases the price of this latter quantity will not be one-half the amount that has

to be paid for the one ton of the superior coal. On the other hand, a vessel requiring, say, one thousand tons of English coal, would have to carry fifteen hundred tons of country coal, thereby depriving the owners of space for five hundred tons of cargo. This it is which makes English coal so extensively used on board of steamers, even at its relatively higher cost price. Besides the driving of machinery, there are, however, many ways in which this coal might be used. There is a continual cry that the country is being deforested for fuel. In the early days of the use of coal in England, it was much hated, and stringent laws were passe regulating its use, and confining the burning of fires to certain hours. Now, who could do without the coal fires? Can nothing be done to introduce coal as a domestic fuel in India?

The cost of carriage is certainly a serious drawback, but at least, within reasonable distance of the mines and of the railway, it ought not to be too dear. Coal is four times more valuable as a heating agent than wood, and its price need seldom be more than double that of wood. True, different appliances are used, but we may trust native ingenuity to tide us over this difficulty. Of the quantity of coal brought to the surface (1,015,210 tons) 957,248 are from the mines. The output of the various districts is as follows :—

Bengal.	*Tons.*	*Per cent.*
E. I. Railway mines	301,976	30
Other mines	655,267	64½
Total, Bengal	957,243	94½
Mohpani	12,758	1
Warora	35,209	4½
Total	1,015,210	100

The output at the Warora mines has increased largely, the average for three years, 1875-71, having been only 13,229 tons as against 55,109 tons in 1878. This is not surprising, when we consider that the Great Indian Peninsula Railway Company pay an average of £1-7-4 per ton for their coal, as against the East Indian Railway Company's outlay of £0-5-5 per ton for their fuel. The Warora mine lies contiguous to the Nagpore extension, and will find a large sale for its output, as the line extends eastward towards Sumbulpore, Midnapore, and Calcutta. The Mohpani mine, too, will acquire importance when the Bhopal extension of the Gwalior line is continued on the G. I. P. line near Mohpani. Our greatest hopes, however, lie in the Assam district, where there is an extensive field of coal, which will compare favorably with the best English article. At present it is quite beyond our reach, and perhaps it would not pay to work it on the limited scale necessary to supply the Assam steamers. Doubtless this field will be utilized whenever the railways shall go up the valleys of the Brahmapootra the Soormah, and the Barak.—*Indian Daily News.*

THE KARHARBARI COAL FIELD.

THE Karharbari field is not without drawbacks from its value. Mr. Hughes, at the outset of his report, uttered a warning to those who, he said, had strongly upheld its advantages; he said they seemed to have failed to attach sufficient weight to the drawbacks of its limited area, the character of its seams, and its geological structure. The surface of the field is broken by two outliers of the crystalline series; numerous trap dykes run in various directions through the field, and affect the value of the seams; and quartz reefs are common. The disturbance of the strata has been considerable towards the northern boundary, where the dips are as high as 32° and 35° in places, and very various. The beds dip generally from all the boundaries towards the middle of the field, and the intersecting streams do not seem to be at sufficiently low levels to give efficient drainage. Hence arises a cry for more pumping machinery, and the necessity for increased expenditure on "block account," which is always in debt to "revenue." The issue rates, for company's purposes, of coal of all sorts, were increased last year seven annas per ton, with the view of squaring this account before the colliery should be handed over to Government on 1st January 1880. The estimated expenditure on works and new machinery for 1879 was over two lakhs of rupees. In July 1878 a scientific man, Dr. Walter Saise, was got out from England to act as Assistant Manager, and for the rest of the year he was principally occupied in completing the surveys and taking sections through the field, from which he prepared a report showing what remained to be done to develope it. The output for 1878 showed a slight falling off, which was attributed by the Manager to want of machinery, for the working faces of the principal mines had been carried so far down the dip that it was found impossible to keep the workings dry, and half the galleries that should have been yielding coal were full of water.

Indeed it would have been impossible to have complied with the requirements of the Locomotive Department of the E. I. Railway itself, had it not been for one seam in a hill, which was worked by drifts and required little or no machinery. A tramway had been completed to the foot of this hill, but the one locomotive available was in sufficient for hauling the coal, and carting had to be resorted to. The mining in the Serampore part of the field was interrupted by the falling in of the roof of one mine owing to the pillars getting crushed, and the consequent inrush of a neighbouring stream. There are 40 shafts in the Karharbari workings, 35 drifts in the Bhuduah hill, and 18 shafts in the Serampore portion of the field. Of these, twelve, including a quarry, were worked in 1878 at Karharbari, four of them being then nearly worked out, and another about to be closed for want of an engine. Only four good mines, the quarry and the hill workings were left available at the end of 1878 in the Karharbari quarter, some of the others being full of water, and others requiring to be sunk deeper.

Altogether it is clear that the Karharbari field is troublesome, and requires a long capital for its working and future development. Henceforward the Government of India will have to find the money for new works and plant, and not merely to guarantee the interest on it, and in these times of economy they will probably not spend more than is absolutely necessary. At the same time it is of great importance to have cheap coal for working the E. I. Railway, and as this has hitherto been secured by the working of the Kaharbari coal field as a Company's or departmental concern, the same course will probably be continued so far as necessary. But even the E. I. Railway itself, now exists solely for the general good of the country, and no longer for the benefit of the shareholders; and care must be taken that neither it nor its accessory, the coal field, shall be fostered to the injury and the hindering of the development, in parts of the country not traversed by it, of other promising fields of industry. If, for instance, coal for working the upper parts of the East India Railway can be got cheaper from other quarters than Karharbari, it will be the interest of Government, and of the E. I. R. Company, who are hence forward to work the line for Government, to use such cheaper coal irrespectively of where it comes from. And if a new enterprise which promises to supply cheaper coal would also assist in the development of a backward portion of the country, and give it that cheap and rapid means of communication which is now recognized as the best safeguard against high prices of food and famine, it seems to become the positive duty of Government to see that that enterprise shall have fair play, and shall not be sacrificed to any supposed necessity of developing to the utmost the coalfield already in use. Such an enterprise appears to be the proposed railway from the head of the Sone Canals to the Daltonganj coalfield, of which, some four months ago, we gave an account, moved thereto by the uninformed notice of an up-country contemporary. The Daltonganj coal is only about 113 miles from Buxar, or 139 miles nearer that point than the Karharbari field is. And it has been calculated that the Daltonganj coal could be sold at Buxar—to yield a handsome profit on the construction of the 62 miles of railway that would have to be made to bring it down to the head of the Buxar Canal—for Rs. 10 per ton. The cost of Karharbari Coal, at Buxar, to the Locomotive Department of the East Indian Railway, at the present rate of issue at pit's mouth, *plus* the rate of frieght given in the company's published tariff for last September, is Rs. 11-6-4 per ton; and the cost to the public and to foreign railways at the same place and at the published rates, is Rs. 13-15-4 per ton. The saving to the East Indian Railway Company, or now to Government, by the use of Daltonganj coal, which is practically as good as Karharbari on the whole length of line west and north of Buxar, would therefore be Re. 1-6-4 per ton, and to the public and to foreign railways Rs. 3-15-4 per ton. It does not affect the argument for the substitution of Daltonganj for Karharbari coal that the E. I. Railway Company has been in the habit of allowing special rates of freight, lower than those in their published tariff, to certain other railway companies, or that, moved probably by the rumours about Punjab coal mines, they have recently advertised a general reduction in the rate of freight of Bengal coal (by whomsoever owned) from 5·76 to about 3·5 pies per ton per mile. All this only means a diminution of carrying profits; and, as the profits will henceforward belong to Government, it will be for Government to make such re-adjustment of rates as may seem best for the general interests of the country. To carry coal produced by other coal owners for other railway companies at unremunerative rates, will not compensate for the loss incurred by burning dear coal in one's own locomotives, and especially also if the opening up of a whole administrative division of country is thereby prevented. Cheap coal for the East Indian railway has hitherto been secured by the guarantee on the part of Government of 5 per cent capital expended by the East India Railway Company. Now that this is no longer possible, Government have the power of securing it for the upper portion of that line, as well as for all the other lines in Upper and Central India, by the smaller guarantee of 4 per cent. on the capital required for the construction of a railway into Palamow. This question only requires to be dragged into the light of day; and the railway companies in Upper India, who now pay so dearly for Bengal coal, will be glad to hear that the question is now at last under the serious consideration of Government.—*Englishman.*

FORESTRY.

THE French preserve timber with lime; the planks are placed in a tank, covered over with quick lime, and then stocked with water; they are allowed to remain thus for a week or so.

THE Lieutenant-Governor of Bengal is pleased to order that, on and after the 1st October 1880, the following shall be the rates for forest produce in the Sunderbuns Protected Forests in supersession of those published in Rule 1 of the Rules of the 17th August 1880 :—

(1) On every maund of sundri, pussur, or amoor timber ... ... one anna.
(2) On every maund of keora timber ... ... one-half anna.
(2) On every maund of any other forest produce... one-quarter anna.

THE Forest Department is very far from being held in the "full odour of sanctity" by our mofussil fellow-subjects. The inhabitants of the Talukas of Mahim and Dahanu, in the Tanna Collectorate have addressed to the Revenue Commissioner of the Northern Division what they modestly term a petition, but which is in fact an indignant remonstrance against the systematic piece-meal encroachments of Government upon the rights of landholders, never disputed up to the time of the English advent nor even then, until it became the misfortune of this country to find itself under the direct rule of home authority. These people complain that the ever-increasing restrictions in the Forest Laws have, at length, drawn the string so tight as to preclude the owner or holder of land from taking from it as many sticks as will make his kettle boil. To begin with, his land is rack rented and assessed at rates from which he can scarcely hope to scrape the means of existence, he is next told that he must appropriate some portion of the land he pays for, to the continued growth, on behalf of the Government, of such forest trees as the Collector, not he, may think desirable. Injustice, it would be supposed might have ended here, but it did not. It was thought that another turn of the screw might be ventured upon, and even the brushwood was seized upon, thus denying—except for a consideration—that common right to the fuel of the forest, which since forests came into existence was never before known to be disputed. Has the Government of this country fallen into such abject poverty, as to necessitate this huckstering for a few rupees' increase of revenue?

THE *Indian Forester* for July says:—

Under the head of *Official Papers* are published important despatches regarding the staff of the Indian Forest Department, the most noticeable feature of which is the employment of native agency on a greatly extended scale. Sub Assistant Conservators are in future to be recruited from the ranks of native candidates, who will be specially instructed, and who will be eligible for employment as Assistant Conservators, as vacancies occur. If as Assistant Conservators, then why not in due course as Deputy Conservators, and so on? No doubt this will be eventually carried out, and the department will *in time* be filled almost exclusively by natives, who will receive the same salaries as Europeans, so no saving will be even effected thereby. For the present however, half-a dozen "thoroughly competent candidates" are to be selected annually in England to fill the posts of Assistant Conservators. We regret to have to demur to the correctness of the statement of the Government that "great care and educational tests and other special qualifications were rigorously insisted upon" in selecting "the considerable number of men" appointed to the department in this country.

IT is a matter which ought to attract the serious attention of the Government, says the *Bombay Gazette*, that the patches of timber which have in the past been preserved adjacent to each village are steadily disappearing through the demand for fuel to work the steam engines at the different cotton presses scattered over the Berars. In the compound of each cotton press there is stacked a quantity of timber sufficient to keep the engines going for months to come. The high price of coals renders it more economical to burn wood in the furnaces, and the consequence is that village babul-bunds are steadily disappearing. Provision should be made to supply the place of the timber cut down by systematic planting of young trees. Without the order of superior authority nothing will be done. The re-afforesting of certain parts of the territory is a work which should be undertaken at once, and the old babul-bunds should be preserved, and, if possible, extended by the direct intervention of the executive, for nothing else will suffice.

THE conservation of forests which the Government Forest Department has so far effected, cannot but have a beneficial result in proportion to its extent, which, as compared with the vast size of our Indian territory, seems but small as yet, the whole area at present protected being only 18,113 square miles. It has been said indeed that the deprivation to the ryot, in the protected districts, of the fire-wood, which is now no longer available to him, causes him to burn for fuel the manure which would otherwise be thrown upon the land. But the average consumption of manure for fuel common to all India, evil though it may be can be very little increased by forest conservancy, while the benefit which will ultimately accrue from the increased quantity of fire-wood, which the forests will produce, will more than balance the loss to the ryot. The more woods we call into existence, the better for the future generations of ryots, and portions of them may ultimately be set aside expressly to meet the demand for fuel; then, it is obvious that the reckless cutting down of young trees must be prohibited while the first steps for creating forests are being made.

THE Bombay papers are protesting against the way in which the scanty patches of timber in the Berars have been used up to provide fuel for the numerous steam engines scattered over the country, and they call upon Government to interfere to put a stop to the entire denudation of the country. It is much the same in other parts of the country. Although we have expensive and extensive branches of the Forest Department established for the conservation of our timber tracts, we are afraid the most important work entrusted to the officials is to a great extent neglected. It should be insisted upon, that wherever a growing or full grown tree is felled, saplings should replace it in the proportion of three to one. There can be little doubt but that the reckless denudation of the country of its timber growth is surely inducing climatic changes of a deleterious character. It has much to answer for in bringing about the decreased rainfall of recent years, and, if persevered in, will in all probability turn some of India's most fertile areas into so many Saharas. Too much attention cannot possibly be devoted to forest conservation in this country.

THE PINE IN BURMAH.

A WORK recently published by Mr. Kingzett, a Fellow of the Chemical Society, entitled *Nature's Hygiene*, sets forth numerous examples of the chemistry and hygiene of the eucalyptus and the pine. It seems that the valuable disinfecting properties of the Australian eucalyptus trees, which have been proved in many feverish and marshy localities in Europe are possessed in a larger degree even by the pine. The quantity of oil of turpentine that finds its way into the atmosphere from a pine forest, especially in hot weather, is simply incalculable. Valleys and swamps may by this agency be freed from malarial fever, and, in the place of a poisonous atmosphere, these trees substitute a state of balminess and purity at once luxurious and healthful. We believe Mr. A. H. Hildebrand, the present Assistant Commissioner of Engtsein, when he was in charge of the Salween district, drew attention to the pine trees which existed in that region. The head quarter town of the Salween district, Pahpoon, is noted for the dangerous fever which prostrates all new comers for many months, and attacks even the seasoned foresters who pass through it *en route* to Zimmay or the red Karen country. We understand a European forest officer also now has his head-quarters at Pahpoon. Might it not be advantageous to the health of the residents in this feverish locality if he were directed to form plantations of pine at or near Pahpoon. The wood itself perhaps may not be of much use, exceeded as it is in hardness and all enduring qualities by teak and many other descriptions which have their habitat in the Salween valley. But as pine is found in large quantities in this district it should not be difficult to obtain a sufficient quantity of young trees to form a sufficiently large plantation and purify the malarial influences of the head quarter town. Every European officer who has been quartered in this town has hitherto had to claim leave after a few months' residence, so prostrated have they been from fever. The Burmese and Shans also suffer in a lesser degree, and, though we have made it the head-quarters of the Salween district for many years, we have not done anything to improve the health of the place. It seems, if the reports by Mr. Kingzett are correct, and we have no reason to doubt them, that we have in the pine tree a preventative of malaria and fever which should be tried forthwith at this feverish out station. We believe, when Mr Hildebrand made his report on the pine trees of the Salween district, a paper on the subject was published in the *British Burmah Gazette* and experiments made on the turpentine which could be produced from the Salween pine. But, although these seem not to have been commercially successful, for we have heard nothing more about them, there is no reason why the hot weather of Pahpoon should not make a pine tree plantation there give off a sufficient quantity of oil of turpentine to the atmosphere which would replace the present poisonous atmosphere and remove the stigma which Pahpoon at present labours under of being the most pestilential station in the whole province of British Burmah, not even excepting the Arakan Hill tracts.—*Rangoon Gazette.*

GARDEN.

DR. KING, Superintendent of the Calcutta Botanical Gardens, makes the following observations regarding the *Guango* or Rain-tree. "This wonderful tree grows faster than any hitherto introduced into Bengal with the single exception of the *Casuarina.* It gives a beautiful shade and yields a pod with a sweet pulp, which is greedily eaten by cattle. For avenues, cantonments, squares, and situations where dense shade is wanted, no tree is more suitable than this."

A CORRESPONDENT writes to us from Cashmere, under date September 3rd:—Some time ago Monsieur Ermans, the Superintendent and Manager of the Maharajah's vineyards, imported from Champagne some valuable grape cuttings. These flourished luxuriantly under his care, and to-day, a very interesting ceremony was performed, *viz.*, that of cutting the first cluster of French grapes grown in Cashmere, and, if I am not mistaken, in India. A number of gentlemen who witnessed the ceremony were subsequently entertained at a sumptuous *déjeûner* by Monsieur Ermans. The wines drunk at this repast were all of local manufacture and were pronounced by one or two connoisseurs present as very good. Monsieur Ermans proposed the health of H. M. the Queen-Empress, which was drunk with honors.

A VERY praiseworthy endeavour on the part of the Agricultural and Horticultural Society of India, has been made to test the real value of the properties ascribed to the juice of the *Euphorbia* in the preservation of iron and wood. This plant would seem to have its main habitat in the Cape Colony, and the Secretary of the Society addressed a letter on the subject to Mr. MacGibbon, the

Superintendent of the Botanical Gardens at Cape Town. The reply, however, though clear, is by no means conclusive, that any real virtue has so far been discovered from the applicaton of this sap. Rome, however, was not built in a day—northe virtues of gutta-percha discerned in a year. There is something yet to be made out of that *Euphorbia* milkjuice as an antiseptic.

The famous valley of roses, in the neighbourhood of Kazanlik, in Roumelia, is said to be covered this year by a perfect sea of flowers of the most glorious kinds. This valley is wholly set apart for the cultivation of roses, out of which is made the *attar* so highly valued at Constantinople and elsewhere. The sight now afforded by the virgin forest of rose-bushes, covered with flowers, is unique. One sees nothing but roses from every hill top For miles round, the air is heavy with their delicious aroma. The valley is annually hired out in lots, and most of the contractors are English and Russians. Eastern Roumelia used to collect in yearly taxes, from the valley alone, a round sum of over two millions of francs.

ON HARDY LILIES.

No more beautiful tribe of plants, whether hardy or tender, can be named than the genus lilium. Their superb, pure, and pleasing colours, their stately and for the most part refined aspect render them invaluable decorative plants. Their cultural requirements are in most cases simple—they succeed well in any good garden soil, but best in that which is rich, deep, and well-drained. The proper time to plant the roots is as soon as the growth is ripe—that is, when the stems die down. Very usually they are kept over winter in a dry state, and planted in the month of February or March where they are to grow and flower; but this is an evil practice, leading to the weakening of the bulbs, and eventually, if continued year after year, causing the death even of the most vigorous sorts. When the roots are lifted with the view of being replanted, let any fresh, healthy scales of any variety that happens to be scarce, be carefully kept and planted thickly in sandy soil. In the course of three years these will form excellent flowering roots. Lilies delight in high culture. They will take almost any amount of manure —cow manure being the best. Some species are very liable to suffer from damp in winter. A good plan to prevent loss in this way is to cover the surface of the ground with exhausted tanbark or coal cinders to the depth of two or three inches, to absorb and throw off excessive wet. Nearly all the species and varieties are found of peaty compost, but good, well-decomposed manure suits all of them fully better, and is more easily obtained than the best quality of peat. It is the custom of some cultivators never to disturb their lilies after planting them till they show signs of falling off in vigour. Our practice and advice is to lift and replant every second year; and if our land were very light and hungry, we should do so every year, as soon as the first indications of decay manifested themselves. Never leave lifting and replanting of stock in hand longer than this; shop or imported roots you can only plant when you get them in possession; but if the weather and condition of the soil are favourable, plant them without delay when obtained. The most favourable weather for planting is fair and sunny, and the best condition of the soil is when it is so dry that it will not clog the tools.

The above remarks have been based on the requirements of such species and varieties as will succeed well in the open border. There are many sorts which will not succeed without very special conditions; but these we have at present excluded from our selection, and also from any consideration in our cultural remarks. In a general way lilies are benefited by partial shade and shelter in spring and early summer. Shelter especially from cutting east winds and spring frosts, is indispensable to protect the young growth. Hence the advantage of planting them in the bays or openings on the margins of beds or borders of shrubs, where their young growths will receive such open protection as they need. The following selection includes the hardiest, most distinct, and beautiful sorts

Lilium bulbiferum.—Of this species there are many varieties, distinguished by differences in colour, and also, somewhat by, differences in stature and the size of the individual flowers. All are beautiful, and the type is popularly known as the 'orange lily.'

L. candidum.—This is the common white lily, one of the handsomest flowers of June and July. It requires a little shade and shelter to bring it to perfection, the foliage being very apt to be destroyed in spring, by wind or frost, and to be scorched in summer before the flowers become fully developed. There are some varieties of this species, but we consider the ordinary pure white form the most desirable. The double-flowered variety has the merit of more durable flowers, but the beautiful symmetry is somewhat marred by the doubling process.

L martagon.—This is the true 'Turks cap,' lily, so called on account of the resemblance of the fully expanded flowers to the form of the turban of the Turk. *L. chalcedonicum*, the so-called scarlet martagon, is not really a form of the true martagon, but a true species and one of the most beautiful—certainly unequalled in the brilliancy of color, which is vermillion scarlet of the richest possible hue. The martagons being all rather tall-growing species, should have background positions.

L. longiflorum.—Of this there are several varieties, all being dwarf growers. The flowers are white, very long in the tube, and very handsome.

L. tigrinum.—This is the common 'tiger lily,' of which there are many varieties, including a double-flowered one which should be in every garden. It is in all its forms one of the hardiest and most robust of the species.

All the forms of *L. speciosum* succeed well in the open ground though generally grown in pots in frame or green houses. When attempted out of doors, they should be placed where they can be sheltered as they may require protection in spring.—*N. B. Agriculturist.*

TEA.

Green-fly blight has, we learn, been generally bad this year on the Assam tea plantations, and will materially affect the outturn.

Tea planters on the Neilgherries will see from the *Fort St. George Gazette* that the Commissariat Department is asking for tenders for the supply of 110,871lbs. of tea. Tenders may be sent in at any time before the 9th November next.

From some statistics prepared by the Board of Revenue in the Madras Presidency, we learn that tea cultivation is confined to the Nilgiris where there are 79 estates which comprise an area of 9,002 acres: of these 4,831 acres were taken up and planted, 2,543 acres with mature and 1,628 acres with immature plants. The approximate yield of tea was 645,126lbs. last year, giving an average yield of 253lbs. per acre of mature plants.

The Kumaon correspondent of the *Delhi Gazette* hears various reports as to the yield of tea in that district, ranging from 1½ maund to 4 maunds, according to cultivation and situation, and as high as over 5 maunds per acre under very favourable circumstances.

An Association has been formed in London to sell pure Indian teas in packets both in the United Kingdom and on the Continent. The Association will work under the auspices of the Indian tea districts, and is, it is said, prepared to embark on the enterprise on a large scale. This should be good news for the tea interest.

The fall in the value of tea in England is quite a phenomenon and is not confined to Indian tea alone. The *Times* calls attention to what it terms "the extraordinary figures of the tea trade as exhibited by the trade and navigation returns for the month of July last. According to these, England imported in that month 21 per cent. *more* tea than in the same month of 1879, but the value of it was 23 per cent *less*. As the *Times* remarks: "Figures like these must indicate severe loss somewhere."

A better feeling is latterly reported in the English tea-market, partly owing to the prospects of a good harvest, and partly to the fact that all good first chop teas have reached a fair and safe level. Shipments of tea from China are below those of last season. Up to the 23rd instant, the amounts advised as shipped were 88 million lbs. against 99 million lbs. at the corresponding date a year ago. There is an increase of four milions from Shanghai and Hankow, but a decrease of six millions from Foochow. Good export orders are also daily relieving the stock at home, and with the large delivery figures confidence is being restored, and there has been little forcing lately to effect sales. The stock of tea at the end of July in the bonded warehouses of the United Kingdom amounted to 67 million lbs. against 64½ million lbs. a year ago.

To the end of August, the exports of cinchona from Colombo this year amount to 1,135,236lbs., and of tea to 102,452lbs., while up to the 21st ultimo, the quantity of coffee shipped was 618,222 cwts., as compared with 809,433 cwts. at the corresponding period of last year. The *Ceylon Observer* says: "It is evident from the large number of tea seed and plants (chiefly from Assam varieties) which have been distributed throughout Ceylon during the past year, that the tea enterprise here is destined to be one of the chief supports of the planters in the future. One planter alone has sold Rs. 15,000 worth of seed and plants during the last twelve months. The retail price of Ceylon tea in the island is, however, still not less than Re. 1."

The use of limestone appears to be entirely neglected as a manure in India, though its renovating properties are well-known to the Khasias who (if possible) always select limestone reefs as sites for their *pân* gardens, while the Sylhet orange groves near Shellapunjee owe their prolific crops undoubtedly to the mixture of lime and sand in which they grow, as also to the fact that they are inundated several times throughout the year with water impregnated with lime. One look at the vegetation in the neighbourhood of lime deposits indicates what a powerful nourishing agent lies ready to the hands of tea-planters, and yet all manner of expensive manures are sent up to Assam, ignoring or oblivious of the fact that the basis of most of them abounds in profusion within reach of all.

A Luckipore tea-planter was disagreeably surprised one night recently by being awakened by a number of armed men got up in the usual burglar fashion surrounding his bed, threatening to kill him if he called out, and demanding the key of the safe. The gentleman naturally complied with the request, as his refusal would probably have cost him his life; and the dacoits went off with all the rupees and pice they found, leaving the currency notes alone. This robbery was evidently a well-planned one, and it ought to be a lesson to tea-planters, who very often have large sums of money in their bungalows. Every coolie on an estate knows when the monthly garden remittance arrives, and it is easy enough for them to arrange so as to enter the house when everybody is asleep and capture or intimidiate the manager, secure the key of the safe, open it, take away its contents, and disappear long before there was any possibility of the unfortunate planter being rescued or of their retreat being cut off. The lesson to be learned from this case is that no planter should keep a large sum of money

in his house at any time. If he does, he simply offers a premium to the badly disposed amongst his coolies to combine and rob him with impunity.

The difficulty of obtaining a sufficient amount of labour, which has so long been the bane of the tea industry in India, seems now to have been removed; not by the repeal of the objectionable and over-restrictive Act of the legislature, but in consequence of improved facilities for the migration of coolies to the tea districts, better sanitary arrangements, and a general improvement in their condition. This has been so far accomplished voluntarily by the planters themselves, and has led to an influx of labour such as the *Indian Daily News* thinks, reaches the turning point of the great impediment. Time-expired coolies who were imported under the provisions of the Act, are now willing to enter upon new engagements irrespective of that Act; and with the same freedom a very large number of labourers are making their way to the tea localities for employment. The effect of these improvements is made apparent by the importations in 1878 and 1879 respectively. Whilst in the first of these years, 27,362, and in the second 15,619 were imported under the Act, the number of non-Act coolie immigrants were for the first of these years 15,699, and for the second year 9,093. It is now manifest that the Government would have acted more wisely in assisting this important industry by facilitating in every possible way the means of communication, than by instituting obstructive measures, and exhibiting systematic indifference on the subject.

LABOUR EMIGRATION TO ASSAM.

At a meeting of Planters of the Habbigunge district of Sylhet, held at Chandpore, on the 6th September 1880, to consider the subject of the letter from the Officiating Secretary to the Chief Commissioner of Assam, it was unanimously agreed :—

1. That coolies recruited under Act VII. be put under a five years, agreement, instead of, as at present, three years.
2. The employer would thus be enabled to reimburse himself for the heavy expenditure involved in recruiting.
3. This being the case, recruiting would become more general; the result would be that the labour market would get well stocked, paving the way for the time when tea gardens will be worked with free labour only.
4. On the other hand a five years' contract might influence the labourer against immigration, while his earnings as a skilled and acclimatised factory hand would not increase, as at present, on expiry of his three years' service.
5. To obviate the first objection, and to give justice to the coolie, while at the same time securing his services to his original employer for the term of five years, we are of opinion—

1st.—That the labourers' wages should be increased by Rs. 1 per month during the last two years of his agreement.

2nd.—That the punishment provided by the Act for absence without leave, or refusal of duty, is inadequate and might be more severe.

3rd.—That recruiting by garden Sirdars should be entirely unrestricted. If necessary, Government supervision only to begin at the place of embarkation.

4th.—That the limit of the price at which rice is to be supplied to coolies be raised from Rs. 3 to 3-8.

5th.—That Act XIII. should be for the tea districts as nearly as possible assimilated to Act VII. as far as regards the provisions made for the apprehension of run-aways, punishment for absence without leave, and refusal to do duty, or that Act VII. should provide for the taking of local agreements without a tax being levied on the labour thus engaged, and in other respects providing for the circumstance under which local agreements are taken.

COOLIE LABOR AT THE TEA GARDENS.

The following article from the *Indian Daily News* contains some useful information :—

The turning point in the all-absorbing question to Tea-planters—that of the labor difficulty—seems to have been passed. The numbers of coolies imported are visibly declining,—we mean the numbers imported under Act VII. of 1873 (B.C.)—while an ever increasing number is reaching the tea districts on their own account, and freely entering into service outside the pale of this Act. During 1878, the total numbers imported by the several gardens, were much higher than those in 1879; for instance—

		1878.	1879.
Act VII. coolies	...	27,862	15,619
Non-Act coolies	...	15,699	9,093
Total	...	43,061	24,712

That this is caused more by the improvement in the communication between the recruiting district and the garden, will be seen by a glance at the following table for 1879 :—

	Act VII. coolies. Coolies.	°/o	Non-Act coolies. Coolies.	°/o	Total. Coolies.
Sylhet	401	25	1,218	75	1,619
Cachar	3,077	69	1,381	31	4.458
Kumroop	134	22	486	78	620
Durrung	2,358	68	1,135	32	3,493
Nowgong	1,389	67	679	33	2,068
Seebsaugor	4,251	63	2,502	37	6,753
Luckimpore	4,009	70	1,692	30	5,701
Total	15,619		9,093		24,712

From this, it will be seen that those districts, favorably situated in regard to communications have imported more non-Act coolies than the others, and we can look to Assam being soon released from the vexatious operation of the Act altogether, by the efforts that are being made on all hands to improve her means of communication. The Assam Immigration Report for 1879 tells us of much improvement having been effected in the means of transporting immigrants into the tea districts. More strict regulations have been put in force on board of the steam vessels conveying the coolies, and in other ways, the general comfort of the immigrants has been attended to. One lakh of rupees has been sanctioned by the Lieutenant-Governor to be expended on improving the road between Dhoobree and Kaunia. This has been obtained from the Labor Transport Fund, and the accumulations of that fund could not well be spent in a better manner. The mortality tables show an improving state of affairs, notwithstanding the fact that the death-rate, comparatively low as it is, is still very high. Among non-Act coolies, it has fallen to 26·9 per thousand per annum, while among the Act VII. coolies it is 56·8. This latter high rate is, no doubt owing to the fact that the majority of the Act VII coolies are comparatively new arrivals, while many of the others are old acclimatised coolies, whose agreements have expired, and who have entered into fresh contracts under the ordinary civil laws; while the remainder, men who have marched on foot most probably all the way from their homes, are likely to be strong healthy men. In some districts, the mortality is still very high, notably in Durrung, where it is recorded as 85·3. If this be the normal health of imported laborers in that province, it almost becomes a question whether humanity should not intervene to prevent immigration where such occurs. Among non-Act coolies, the mortality in Durrung is 31·5, and Nowgong is not far behind it. The mortality in Assam among infants averages 67·9.

Regarding the working of Act VII., the inspectors report, that "a uniform readiness is shown by employers in carrying out suggestions for improvements," and that no special cases of ill-treatment of laborers were reported. Improved sanitary arrangements have been freely introduced, and everything reasonably expected has been done towards increasing the comfort and health of the laborers. It hence becomes a question whether the stringent provisions of the Act, as applied to employers, might not wisely be somewhat relaxed. The tea industry has long struggled under many difficulties, not the least of which have been the labour question, and the operation of Act VII., and now that inquiry is being instituted into this latter question, it might be a graceful contribution towards a revival of the industry were Government to remove a number of vexatious enactments, which press hard on the employer, and which are unfair in principle as well. The Chief Commissioner is perfectly correct in largely ascribing the high mortality to the unsuitability of the food, which the imported labourers are in a measure compelled to eat. Many of them come from districts, where the prevailing diet consists of barley, peas, millets, and Indian corn. When these men reach the tea districts, they are compelled to subsist on rice, and it would be wise on the part of employers, if they would take steps to import more suitable food for their laborers. If the obnoxious rice clause were abrogated, they would perhaps be more inclined to turn their attention to this very important matter. While rice is the staple food of the province, we are a little surprised that the employers should not encourage its cultivation. Almost every garden possesses large tracts of land, unfitted for tea, but suitable for rice cultivation. A little encouragement by way of cheap or free leases, would perhaps induce villagers to cultivate these patches, and thereby increase the local supply, while materially adding to the general healthiness of the country by reducing the area under jungle.

A PHASE OF THE TEA MARKET.

The *Times of India's* London correspondent writes :—

The shareholders in Indian tea gardens have suffered so severely from the year's work that they have been naturally eager to seize any straw to float to safety; and hence the airing recently of a variety of remarkable projects for the popularisation of Indian tea. There are several causes for the depression in the trade, and I have so frequently enlarged upon them that I need not now recall them; but attention has now been directed to a cause of serious loss, of which ordinary shareholders in tea companies are probably quite ignorant. Formerly, all Indian teas were put up for auction in London; the immense competition existing among the London dealers prevented a parcel going below its value. Jealousy of each other made them eager rivals; and public sale was one of the surest modes of obtaining fair value. But, for some years past, a new mode of disposal of Indian tea has come into being in the provinces. Certain people have been offering Indian teas direct to the country dealers by persons who (since they accept ruinous rates, and always below the market) seem to have no other object than the making of their commission. The effect is that the London dealer, constantly having before him particulars of sales made in the country, finds that his standards of values are too high; and he argues that, if such teas are being sold to his customers, he must see that he buys at corresponding prices, allowing for the risk he takes in holding stocks and waiting his chance of the market. In this way the new system breaks down the market, and reduces the dividends of the tea companies. The theory is one obviously advanced in the interest of Mincing-lane; but, while it need not be swallowed whole, there is a good deal of truth in it as accounting for the discouraged state of the market.

INDIAN TEA CULTURE.

IN 1850 the area under plant may be approximately estimated at not more than 1,000 acres, and the total outturn of tea at little over 250,000lbs. At the present time the area under plant may be put down for—

Assam	Acres	85,000	207,600
Cachar	"	47,000	
Sylhet	"	18,000	
Darjeeling and Terai ...	"	34,000	
Dehra Doon	"	4,300	
Kangra Valley	"	7,400	
Kumaon	"	4,400	
Chittagong	"	4,200	
Chota Nagpore	"	3,300	

producing about 40,000,000lbs. of prepared tea, and representing a capital invested not far short of fifteen millions sterling, while about two millions sterling are spent annually in India in the working and upkeep of the plantations. Of the advantages accruing to India—directly to the people, and indirectly to the Government—from the disbursement of so large an amount of money, there can be no question. It will be seen that, of the total area of 207,600 acres brought under cultivation, 150,000 acres lie within the administrative circle of the Chief Commissioner of Assam; and the statistics of that province demonstrate the continuous and rapid progress of its revenue and general prosperity during the period in question,—a prosperity which may be fairly claimed as being almost entirely due to the beneficial influence of the tea industry. There still remains, however, a vast field for future development, not merely in the production of tea, but for almost every kind of crop grown in India, more especially rice.

Tea culture alone, apart from other products, is capable of almost indefinite expansion. Land and capital can be found in abundance, and the sole impediment to its continuous development is the difficulty of obtaining an adequate supply of labour on terms admitting of its profitable employment. The hindrance to progress does not arise from the inability of the industry to afford the wages necessary to render labour highly remunerative to the immigrant, but from the excessive cost of recruitment and transport, largely due, in the opinion of all tea-growers, to the stringency of the labour laws.—*Madras Mail.*

INDIA *versus* CHINA TEA.

A CORRESPONDENT writes to an Indian paper that India is likely to profit considerably by the Sydney Exhibition. Indian tea was scarcely known in Australia previously. An English firm of tea-planters in India exhibited a small trophy of samples of their produce in the Garden Palace, and the tasting of these samples was a new sensation to the Australians. China tea was the only known tea previously, and very poor stuff, it is said, much of it was. The Australians found this to their cost, but they had no alternative. *Now* Indian tea, they say, is all the rage in Sydney. The tasting of pure Indian tea was as great a delight to the Sydneyites as Tasmanian whole strawberry jam to the Victorian miner, whom the protective policy of Mr. Berry's now defunct Ministry compelled to eat the pumpkin trash flavoured with strawberry syrup, which is so largely manufactured in Melbourne. In the bush, tea is the universal drink, and, therefore, the popularity of Indian tea in Australia ought to have a material influence upon the Indian tea trade. If the exports of India could be materially increased, there can be little doubt that the exchange would soon right itself. Year by year India is gaining upon China in the export of tea to England and its colonies. Twenty years ago, China commanded the tea markets of the world, but as Indian tea becomes better known year by year, this supremacy is destroyed. Up to 1876 the demand for Chinese and Indian tea was equally increased. Since then the whole increase has gone to the credit of India. It appears to be only a question of time when India will have a monoply of British supply. Japanese tea is similarly ousting Chinese tea in the markets of the United States of North America. More than a third of the tea consumed there comes from Japan now. So that without greater care to the manipulation of the leaf, and improved methods of culture, the loss to China will be very considerable. Hitherto this loss has been little felt, however, because the silk trade has developed so wonderfully. There is, perhaps, no country in the world where the planting cultivation, picking, and firing of the tea are more skilfully done, better attended to, or performed with more profitable results on the produce, than in India. And practically there is hardly any limit to the amount that can be raised. There is now under cultivation in India as much land, if raised to its full tea-bearing power, as would supply the entire British demand—including North America, the Cape, and Australia, whilst, if the cultivation extends in the future as it has done in the past, there will be, in ten years, land enough under tea cultivation in India to supply all the world. For strength of flavour, I was told there is none superior to that of Assam, Sylhet, and Cachar, whilst the various growths of Darjeeling, Kumaon, and Kangra are equal in aroma and delicacy of flavour to the very best brands imported from China. The Kangra is to ordinary Chinese tea what Chateau Margaux is to *vin ordinaire,* and the most prejudiced of English tea-drinkers are beginning to become convinced of this fact. But it takes time to remove prejudices, particularly in the matter of eating and drinking.

TEA ADULTERATION.

SPECIAL attention has of late been directed in Europe to the sophistication of the leaf whose infusion makes the chief beverage of millions of people in Europe. England and Russia are the chief consumers, in that continent, of the Chinese product. France takes two hundred times less than Great Britain; but, notwithstanding this, it has fallen to the lot of a French chemist to illustrate adulterations which have heretofore been unsuspected in London. It is not the constituents which are employed in firing the leaf, whether in China or Japan, for foreign consumers, that are chiefly disagreeable or baneful. The comparatively very small quantities of gypsum, Prussian blue, indigo, and other substances, which are used in the pans for the purpose of imparting a face to the material, have often been pronounced by competent authority practically innocuous. Why tea-drinkers should prefer to have their drink impregnated with ever so small a quantity of avoidable dirt to imbibing the pure and simple decoction of the plant prepared without it, may be a matter of mystery; but it is not our present purpose to inquire into the cause of this or any other anomaly in the matter of the state of nations or individuals. Our desire is to sound a note of warning to those who, by fair dealing and the provision of an all but unimpeachable article, have secured for their wares a mart the profits from which are adequate, and may be reckoned upon with certainty for a distant future, so long as attempts are not made to enhance them by fraudulent practices. As with silk so with tea, Japan has attained in America a very high reputation for the integrity of her merchandize. It would be suicidal to jeopardize it by introducing a system of adulteration into her exports. A Chinese poet wrote of tea that "it tempers the spirits and harmonizes the mind; dispels lassitude and relieves fatigue; awakens thought and prevents drowsiness; lightens and refreshes the body, and clears the perceptive faculties." When impregnated with the ingredients used to falsify it in China and at home, it can hardly be expected to retain those attributes. The "Maloo mixture," which people attempted some few years ago to make in China, did serious damage to the trade of Shanghai: and yet it was not much worse than many of the other "lie teas" which have been so largely exported thence, and whose histories and composition are wonderful exemplifications of misdirected industry.

We have all known, probably for as long as we can remember that sloe leaves and other products of English hedgerows and, shrubberies, to say nothing of the expended refuse of the teapots of hotels and coffee-houses, are no strangers to the stock in trade of the country and metropolitan grocer. Catechu and sumach leaves, entirely innocent of connection with the frauds of *thea bohea* or *thea viridis,* have mixed together in ascertained proportions and christened with high-sounding names, been palmed off upon an easily deluded British public as a tea possessing "four times the strength of the strongest tea previously known." Perhaps the compound justified the assertion, but certainly not in the sense in which the consumers understood it. Again, in former years a "Chinese botanical powder" which had some vogue, was found to be little more than a composition of catechu (the product of the *Gambir Acacia*) formerly and erroneously known as *terra Japonica* and ordinary wheaten flour. Still more patent devices were those not very long ago, if they are not still, resorted to by celestials to add weight to their wares. Leaves ingeniously enclosing iron filings were shipped away by the chest. Less audacious but scarcely more justifiable schemes were, and are now, resorted to, in order to give false or inferior articles the semblance and aroma of excellence. Olives, gardenia, and jasmine have all had tribute taken from them to supply the tea-chest; and it is notorious that a certain kind of camellia is largely cultivated in special districts of the neighbouring empire for intermixture with the genuine leaves. The willow, again, does very extensive duty on behalf of the counterfeiter. During April and May its twigs are pillaged of their growth, which, after being subjected to a slight fermentation, is carefully dried and rolled, and dusted into green tea to the extent of ten or twenty per cent. This practice, which is described "as ingenious as it is profitable," had its origin in the model settlement of Shanghai about fifteen years ago, and is said by the analyzer to be continually extending. It is odd that the Chinese carry on their operations openly, and indeed neither do, nor need, care about their customers, and they manage to get rid of all their production, spurious or the reverse. What between Mongolian and Circassian dexterity in fraud, it would perhaps be difficult to particularise foreign substances that have not found their way into the bins of the teamen, and then into the cups and stomachs of their customers. Twenty years ago excise investigation had discovered,—in addition to the products which we have enumerated,—contributions from the horse-chestnut, the elm, poplar, beach-plane, fancy-oak, several gums, and other vegetable matter not resembling tea-leaves in any one particular. But organic matter is not sufficiently copious in its resources to satisfy the greed of the dealer. We have said that a little Prussian blue and gypsum and indigo, used in what we will consent to call the legitimate manufacture, may be allowed in deference to the queer taste of foreign fashion. We hardly imagine, however, that "taste" would care to know that it swallows, in considerable quantities, from the uninebriating bowl, sulphate of lime, and such repellent filth as earthy black graphite. Magnesia may have useful effects, which, however, are certainly not contemplated by the dealers who employ it. It is said to aid the water in extracting gluten from the leaf, but this advantage is hardly a factor in the adulterator's motives for adding it to his compound. This may contain also such vile coloring matter as Venetian red, Dutch pink, rose pink, with chromate of lead, carbonates of lime, copper, and magnesia, sulphates of iron, French chalk and in fact almost anything. Whether the headaches and maternal disturbances which are said to be occasionally produced by tea-drinking, may not have their origin rather in the alien matter too frequently present in the infusion, at least in European countries, we will leave to the sense of our readers to determine. A learned authority states that "tea possesses a specific and marked influence over the functions of the brain." He might have added that its abundant concomitants must exercise a "marked and specific" effect upon other organs.

As we have already said, the practices of falsification here alluded to have, at least as far as we are aware, only been applied to the Chinese product, either in the places where it is grown, the ports where it is shipped, or the marts for which it is destined. We have every reason, as we have every desire, to believe that the Japanese leaf, with the exception of the simple and probably uninjurious additions which it receives in the firing process, is uncontaminated. And that this should continue to be the case, all those who look forward to a prosperous and increasing commerce for the growers and shippers in this empire, in one of the most gracious of Nature's gifts to bibulous mankind, will desire. Hence it is important that notice should be taken of very bad news which comes to us from another port. The *Hiogo News* distinctly

states, on what is averred to be direct personal evidence, that hundreds of Japanese were lately engaged, on the hills behind Kobe, in plucking the leaves of the *wistaria* and drying them in the sun. The writer continues :—" These leaves were taken to the village of Kita-no-mura, presumably for the foreign market. On being asked what they were to do with the leaves, the natives coolly told foreigners that they were making tea ! The open and flagrant manner in which the operations were carried on, are not however, so astonishing as the stupidity of the natives in taking this particular leaf for the purpose of mixing it with the genuine tea. In musters which have come to the hands of foreign merchants in Kobe, the *wistaria* leaf has been detected, and no foreign dealer would ever venture to send a consignment of such tea to any house in America ; for if he did, it would be the last he would be likely to send. The *wistaria* leaf is not unlike the tea leaf, except that it is not so heavy ; but it is altogether unsuitable for mixture with tea, for the purpose of increasing the bulk, which is the dishonest purpose the natives have in view. The admixture of itself defeats their fraudulent purpose, for the presence of one leaf of the *wistaria* in a cup of tea is enough to make it undrinkable. It requires no practised tea-taster to discover the presence of the leaf ; any one who has a palate at all can easily tell that there is something very disagreeable in the taste of the tea when this *wistaria* leaf is in the infusion. The result, therefore, is that nobody will buy the tea so adulterated which has been brought to the market." This is of itself a fortunate circumstance ; but when once a nefarious course is initiated, it is only too likely to acquire fresh developments. No one will deny that the preservation and extension of so valuable an industry as the tea export trade, have profound interest for all classes in the country. It might be advisable for the Government to protect the national welfare in this respect by the establishment of a system of inspection of which the growers should bear the cost, which otherwise would not be heavy. Possibly, however, vigilance on the part of the tea-men inspecting and tasting their musters, and stern discountenance and reprobation of dealers detected in dishonest attempts, will be sufficient to meet the emergency. By some means or other, however, producers and brokers must be taught that integrity in this respect will pay better than fraud. A few shipments of adulterated tea from Japan would seriously injure, if it did not destroy, that branch of trade,—an evil consummation which neither native planters nor foreign shippers can afford to see achieved.—*Japan Mail.*

COFFEE.

A CEYLON paper has been comparing the tea-planting industry of India with the spicy isle's great coffee industry. While 40 millions of pounds is the outturn of the former, Ceylon, even at the present time of leaf disease, can show an annual export of 70 millions of pounds of coffee. In their labour supply also, our neighbours are much better off than we are, and large numbers of immigrants have settled down permanently not only as cultivators, but as boutique-keepers, &c. The Indian Government may well take a lesson from the little island in the south.

A CEYLON planter of experience, in one of the older districts, gives what appears to us very sensible advice to his brethren higher up the country who have been complaining so freely of raids on their fowl-houses, bungalows, &c., lately. He writes as follows :—

" By-the-bye, about the lawlessness and robberies in Dikoya and Maskeliya. Has it never dawned upon the parties robbed to look at home for the thief or thieves. Fine, in a round-robin, all coolies, contractors, appu, cook, &c., say 50c. each, and I warrant that the culprits will be caught if this is carried into force. I have done it more than once during my 25 years' planting, and found it answer A1,—far better than constables do." It appears to us to be a safe inference that in two cases out of three where an estate bungalow is robbed, the thieves are to be found among the servants or coolies on the estate, or else they have worked with the connivance of the latter. The ingenuity of the Tamil coolie when he turns thief is far beyond the understanding of the average inexperienced Englishman.

THE coffee leaf disease continues to spread in Java where it has appeared in the Pasaruan Residency, rarely on rich soil, many trees on poor ground being however rendered almost leafless by it. The head-men assert that the disease has always been there, but that it has never had any injurious effects, and always disappears again after dry weather. The *Dagblad* of the 10th July thus describes the Javanese remedy for it :—

" Wherever the disease prevails, the Javanese let the coffee gardens lie fallow for several months. The grass springing up in consequence, they then cut with knives. When dry enough, it is mixed with paddy straw, spread in rows under the coffee trees and then set fire to. It must then burn without much flame in order not to injure the bark and young shoots of the trees, and must smoulder continuously for some time in order to keep up among the leaves of the trees, a constant heat not great enough to injure the shoots, but great enough to cause the diseased leaves to drop off. The trees become thereby fumigated, the appearance of new and healthy leaves follows speedily thereon and the disease germs are mostly killed."

A FORMER writer on Ceylon declared that the merchants of Colombo were in the habit of marking many of their packages of coffee with the word " Mocha " and shipping it home for sale as the produce of Arabia. The statement created a good deal of amusement in Ceylon at the time, but it was little thought that the day would come when this process would actually take place, although indirectly. We now learn that the price of native coffee has been run up to an unusual figure by sudden demand for it on the part of native purchasers for the Bombay market. Inquiries into the cause for this demand show that it is taken for re-shipment to Aden, where it is understood to be blended with Mocha coffee brought down to that port for shipment to Europe.

A CURIOUS discovery is reported by a French provincial journal. Mocha coffee shipped from Aden reaches France by way of Marseilles through Algeria. It is, for convenience of carriage by camels across the African deserts, made up in special packages consisting of a camel's skin in halves, each package weighing about 185 kilogrammes. On opening one of these packages recently, a goat-skin bottle was found, such as is used by the Arabs. Inside this bottle, which had evidently never been used, were found some fifteen letters, written in Arabic, and enclosed in little bags of linen, each letter bearing the seal of a marabout. The theory is that they have come from some caravan which was attacked by Arab robbers. The story has a curious odour of romance about it, and would supply a valuable incident for an Oriental drama. The letters have been sent to Paris to be translated.

COFFEE STATISTICS.

CERTAIN statistics required by the Government of India of the extent of tea and coffee cultivation in the Madras Presidency have been prepared by the Board of Revenue on information obtained from the districts. Coffee cultivation is carried on in seven districts in the presidency, at Vizagapatam, Madura, Tinnevelly, Coimbatore, the Nilgiris, Salem, and Malabar. In the first-named district there are but 6 50 acres under cultivation ; in Madura about 3,000 acres are under coffee, the Dindigul taluq has the largest number of plantations. In Tinnevelly there are 46 plantations, but the area of land under coffee is only 2,679 acres with an approximate yield of 236,302lbs. ; in the Coimbatore district, the averge is larger than in Tinnevelly, though there are a smaller number of plantations, the yield being 105,140lbs. The Nilgiri, district has a large area under coffee, namely, 45,990 acres with a yield of 10,256,125lbs; in Salem there are 10,059 acres under cultivation with a yield of 1,302,960lbs. The estates in the district are chiefly on the Shevaroy Hills, where the average production per acre is returned at 335 against 462lbs on the Nilgiris. In five taluqs of the Malabar district, coffee is largely cultivated, the total of plantations is returned at 14,858—which shows a falling off when compared with the figures returned in the previous year, owing to some of the plantations having been destroyed by fire and have therefore been struck off from the accounts. The acreage under coffee in the Wynaad is given at 65,829 of which 32,197 acres are returned as the area with mature and 6,905 acres with immature plants : 26,727 acres have not been planted out, but will in course of time be cultivated. The total approximate yield of coffee on all the estates in the presidency is returned at 20,381,086lbs,. for 131,353 acres, 62,729 being planted with mature and 12,996 acres with immature plants. The cost of cultivation varies and is returned at Rs. 250 per acre in the Wynaad, against Rs. 86 per acre in Tinnevelly.

COFFEE DISEASE IN NEW GRANADA.

NATURE publishes the following letter from Mr. A Ernst, of Caracas :—The following information about what appears to be a new disease of the coffee tree, is taken from an official letter written on April 29 last, by Mr. C. Michelsen, Commissioner of Agriculture at Bogota, to Mr. Jose Herrera, Vice-Consul of new Granada in this city, who sent me a copy of it, requesting me to give him my opinion about the disease. At first there appear on the leaves small spots of a light-greenish colour, which in two or three days turn brownish, and then appears on each of them a fungus divided in three or more greenish-yellow branches. This fungus is said to be phosphorescent at night, and in places where it is very common, a phosphoric smell is noted (!). After some days the diseased leaves fall off ; the fruits, which also are attacked by the parasite, follow very soon, and the trees are left quite bare. They form, however, new leaves, after some months, but these are again attacked by the fungus. The disease is reported to be more frequent in damp places than in dry ones, its ravages being greatest in plantations where the trees are planted rather close. The fungus has also attacked the shade trees, especially the guamos (*Inga* sp.). Though the description is far from being satisfactory, I think it is pretty clear that the fungus is not the *Hemileia vastatrix* of Ceylonese celebrity. However, it bears a great resemblance to it, so that I recommended to employ fumigations with sulphur under the kind of large umbrella proposed by Mr. George Wall (*Nature*, vol. xix. p. 423). The unusually rainy weather in the last year has very likely much to do with the spread of the disease, which at the same time is a new proof of the eminently fatal consequences resulting from close planting. I have asked for dried specimens of diseased leaves, in order to submit them for examination to a competent mycologist.

CINCHONA.

WE are informed that the Queen has been pleased, on the recommendation of the Viceroy, to confer on Dr. De Vry, of the Hague, the dignity and distinction of a Companion of the Order of the Indian Empire, for his long and valuable services in connexion with the introduction of the cinchona tree into India and the manufacture of Indian quinine.

WE believe we are correct in saying, that it is confidently expected the Government quinine manufactory at Mongpoo will be in a position to supply most, if not all, the quinine required for the Bengal troops in the course of 1881.

IT seems that cinchona cultivation has not proved so successful in Ceylon as was generally anticipated when planting was commenced. It appears that the sub-soil in several parts of the island is not suited to cinchona, and when the trees have sent their roots into the sub-soil they die out in large numbers.

TROPICAL cultivation is engaging a good deal of attention in the United States of America, for not only are coffee and tea to be produced, but we now learn that American exchanges claim that the climate of California, Northern Georgia, and Alabama is suited to the cultivation of the cinchona tree, from which quinine is made, and it is proposed to introduce the cultivation of these trees, and thereby save the expense incurred in sending to South America for Peruvian bark.

ADMIRAL LAPELLIN, says the *Medical Record*, draws attention to a bean (cedron) which is used by the inhabitants of Central America in the treatment of the cold fever, and which is said to be a good substitute for quinine. Dr. Coignard, who obtained the remedy in Puerto Arenas, Costa Rica, obtained favourable results with it, and Dr. St. Pere and Quesuel found it even more powerful than sulphate of quinine. The bean is cut into bits as large as a pea, several of which are given in the intervals between the paroxysms. This almond or bean is obtained from the *simaruba ferruginea.*

A SURE and certain proof of the growing demand for any article is in imitations or adulterations. Viewed in this light cinchona growers should be pleased to learn that a London chemist was recently summoned "for having mixed tincture of quinine, with ingredients or materials so as to affect injuriously the quality or potency of such drug," whereby he had rendered himself liable to a penalty of £50. A sample of tincture of quinine purchased by an Inspector of the Board at the defendant's shop, was found, on analysis, to be more than 60 per cent. deficient, some other comparatively worthless alkaloids having been added. The market price of quinine, it was stated, was about four times that of the alkaloids substituted for it. The sample would have little value as a medicine, and alkaloids would certainly affect injuriously the quality and potency of the tincture of quinine. In defence, it was urged that it was by no means uncommon to find other alkaloids which should not be in a sample of pure quinine. Sulphate of cinquinine, it was asserted, was a common substitute for quinine, and was used at some hospitals.

THE *South of India Observer* has the following regarding cinchona. Mr. Moens, the Java authority on cinchona is expected, shortly to visit the hills, at the invitation of the owner of the Dava Shola Estate. Mr. Moens is so far satisfied with the results of his experiment of harvesting cinchona bark by the scraping or Java process, that he has resolved to abandon mossing altogether. Although the process is called the scraping process, the *modus operandi* is rather that of stripping, the bark being removed down to the Cambium layer. The trees treated in this manner have renewed their bark readily, and, show no symptoms of injury. If the Dava Shola experiment is generally adopted, a seigniorage on moss, which a few years back was recommended to Government, will have to be reconsidered.

A SERIES of careful experiments have recently been tried in the Presidency of Madras and at Rangoon, having for their object, the discovery of the true value of the Sikkim febrifuge as a cure for fever. Long tables are given in the report, which tables we need not reproduce here. The conclusion arrived at is, that it is more effectual than either sulphate of cinchonidine or sulphate of cinchonine. The evidence in its favor is not marked very strongly, and it is proposed to repeat the experiment by the hands of very carefully selected medical officers, with a view to settling the point definitely. The febrifuge is cheap, and if it be found as effectual as the others, a great economy will have been attained. The percentage of cases cured by the sulphates was 87·52 and 87·78 respectively, while the Government febrifuge succeeded to the extent of 91·15. The only drawback found to the more extended use of this new remedy, is the fact of its producing nausea, immediately after being taken. This is occupying the attention of the authorities at Sikkim, and the drawback is being reduced gradually, as the results of careful experiment show.

RESIDENTS of districts where, during certain seasons of the year, fever prevails with uncommon virulence may well congratulate themselves on the new preventive planned. It has been designed by the local Government at Rangoon, that during the coming fever season, small phials of cinchona febrifuge shall be made available for sale to the people at each district and station by such local authorities as may hereafter be appointed. This medicine has been selected to the exclusion of the sulphate of quinine owing to its extreme cheapness, which places it within the means of rich and poor alike. It is sixteen to twenty times as cheap as the quinine, the values of the febrifuge and quinine being respectively, Rs. 16 and Rs. 320 per pound. At the same time the medical opinion is that it is akin, in its action as an anti-periodic, to the same extent as the sulphate of quinine. The Deputy Surgeon-General has accordingly received instructions to have this febrifuge packed in half-ounce and quarter-ounce phials, saleable for 12 annas and 6 annas respectively, for despatch to the different districts, &c.

SERICULTURE.

MR. R. W. MORGAN, Deputy Conservator, Wynaad, has made known to Government, through the Conservator of Forests, the results of his attempts to cultivate the Tasar silk-worm. A Government Order has been published, thanking Mr. Morgan for the information, with an intimation that—

"It will be considered in the Judicial Department whether similar experiments might not advantageously be made in jail gardens, now that Tasar silk is in such demand in Europe"

Another Indian product, though apparently now almost obsolete, is in great demand in Europe, namely, Indian muslin. Would that the Government would take the matter up and resuscitate that industry. The indents from friends in England for Indian muslin are extremely embarrassing, as the article in question seems to belong to the records of ages gone by, whereas the wearing a material bearing the name seems to be at an unreasonable height.

THE Government of India lately called for information respecting the Tasar and other wild silks of India. Dr. Shortt supplied some information on the subject and stated, that at a little expense a large number of cocoons may be procured. He had made attempts to introduce the cocoons on the Shevaroys, but without success. Dr. Bidie stated that there is little practical information regarding these in Madras, as the Tasar cocoons are not an article of traffic, nor the silk a product of the looms of Southern India. Three species of silkworms are found in the Madras Presidency, namely, the Antherea Paphia, the common Tasar silk insect; Actias Selene; and Cricula. The first named insect is common in Southern India, but nowhere so abundant as to induce the natives to collect it or to render its collection remunerative. The second named is sparsely diffused over Southern India, wherever the tree on which it feeds is found. The cocoons although of good colour, are thin, difficult to reel, and of little value. The last named is limited in its range, being confined to Coorg and Wynaad where it lives generally on *Careya Arborea*, but sometimes on the mango which it strips completely of its foliage. Silk is not made from wild worms in Southern India, except to a limited extent in the country of the Nizam of Hyderabad. The Chamber of Commerce informed the Government that they are unable to afford any practical information on the subject of the wild silks of India.

ATTEMPT TO DOMESTICATE TASAR SILK-WORMS.

MR. R. W. MORGAN, Deputy Conservator, Wynaad, has reported to the Conservator of Forests, that he has been continuing his experiments with the Tasar silk-worm.

"After attempting in vain to procure cocoons in this presidency, I tried Bengal, and in April received 275 from Simla. The moths commenced to emerge at once, but the sexes refused at first to unite. This perhaps was owing to the elevation, some 4 500 feet, but after a time a few couples did. The average number of eggs laid was about 270. I noticed that the females were of two distinct types—one being of a rich golden tint, and the others a warm brownish-grey. This latter type varied considerably, some having a reddish tint, whereas others inclined to buff; the males, however, which were invariably smaller than the females, were of a deep chocolate-lake in color, occasionally having a slightly golden or purplish tinge in the wings. The fertilised females were removed into a muslin covered box in which they laid their eggs on twigs of *Eugenia*. On an average they lived about ten days. The eggs were hatched in from 10 to 15 days. I placed the young worms in a large case covered with muslin, in which there was a tin-box filled with wet sand and stuck full of the young shoots of *Careya arborea* and *Eugenia Jambolana.* Finding they preferred the latter leaves, I fed them entirely on them. On the seventh or eighth day they cast their skins for the first time. The oldest caterpillars were hatched some 39 days ago, but are only one inch in length. This has not been from

starvation, for they have been feed liberally and look quite healthy but, I fancy, on account of the exclusion of sunlight which is essential to their well being. The last 10 days I have been feeding them on *Lagerstrœmia* (Venteak) which they prefer to *Eugenia.*

"I have placed several worms out on trees in my compound, but have slight hopes of their escaping their numerous enemies. The total number of caterpillars of various ages in my possession at present is about 2,000, but it can hardly be expected that the whole of these should reach maturity. They are very troublesome to manage on account of their wandering, propensities, and you can scarcely open the box they are confined in for a moment without their swarming out all over the place. They maintain their hold with such extraordinary tenacity that they will suffer being torn in two before they relax it. This makes it very difficult to shift them. The moths almost invariably escape from the cocoo ns through the upper or pedicel end, but I find that about 2 per cent. of my cocoons have been pierced at the lower end.

"In this district the Tasar is but sparingly found, though the climate is undoubtedly suited to it. I have found cocoons here as large and larger than any I have seen from the North. The moths here seldom or ever lay more than one or two eggs on each tree. There are two crops of c ocoons in the year—one in May and June, and the second in October. In this latter the moths do not seem to escape till the following April, laying dormant the six intervening months. This, no doubt, is due to the forests in India being deciduous; for the eggs if laid would be lost through the falling of the leaves to which they are attached, and even if they managed to escape this peril and were hatched, the young would speedily die from want of proper food. The Wynaad contains a vast area of forest, more than half the trees of which are capable of feeding silk-producing caterpillars. The whole of this is wasted; for although the climate is favorable to insect life, yet its enemies are sufficiently numerous to more than keep it in check. Attempting therefore to breed silk-worms in a state of Nature will, I fear, never pay in this district, for though we may protect them from a host of their destroyers, yet there are some, such as the various species of the *ichneumon* flies against the incursions of which I cannot see any possibility of guarding. To breed them, however, under cover, and in a state of partial domestication, is feasible enough, provided the building devoted to that purpose is thoroughly lighted and ventilated, and means devised for preventing the worms from indulging their wandering propensities. If the breeding-shed were made portable, it would, no doubt, be a great advantage, and this might easily be done were it constructed of wood; it could then be shifted (the supply of leaves being exhausted) from one spot to another. "I had hoped to have tried experiments on a larger scale than I have hitherto done, but find that owing to my frequent absences in the district the caterpillars are neglected and die. So great an amount of constant care and attention is necessary for the success of an experiment like this, that a single day or hour's carelessness may render futile the patience and trouble of weeks. I have therefore determined to wait until September next, when I mean to dev ote a considerable portion of my furlough to experiment and to start a breeding establishment."

The Government in an order of the 9th ultimo say that they are "much obliged to Mr. Morgan for this interesting account of his laudable efforts to domesticate the Tasar silk-worm. Copy of his communication will be forwarded to the Government of India, and it will also be printed for general circulation. It will be considered in the Judicial Department whether similar experiments might not advantageously be made in Jail gardens now that Tasar silk is in such demand in Europe."

TOBACCO.

A PROCLAMATION has just been promulgated that his Highness the Maharajah of Travancore has been pleased to deduce the amount charged on tobacco imported into the bankshalls at Alleppey and Quilon from Rs. 110 per candy, to Rs. 90, for the benefit of the people as well as for the encouragement of the trade in this commodity.

A SUMATRA tobacco planter, in the Trincomalee district, is very pleased with the tobacco he has already grown and cured there and says, "there will be crops taken off nearly 150 acres in February and March 1881."

THE cultivation of tobacco in Japan from plants imported from Havana, Florida, and other places, is favourably reported on. Some experiments made have resulted in a plentiful yield of leaves of a quality far superior to the best Japanese tobacco, although the plants were of very common character.

TOBACCO MANUFACTURE IN INDIA.

TOBACCO manufacture is now making a small beginning in India, and though the quality is still susceptible of improvement, the beginning is one full of promise. In the enterprise being carried on at Ghazipore, in the North-Western Provinces, and at Poosah, in Bengal, by Messrs. Begg, Dunlop & Co., of Calcutta, both the cultivation and manufacture are carried on under the skilled supervision of American growers and curers. Some of their tobacco, which the French Consul-General in Calcutta sent for trial to the *Administration des Tabacs* in Paris, has been very favourably reported on and the administration has asked for further and much larger supplies to test it on a more extended scale. The following extracts from a recent report by Mr. E. Buck, C.S., Director of Agriculture and Commerce North-Western Provinces, on the venture at Ghazipore and Poosah, are interesting as showing what can be done by combination of capital, energy, technical skill, and perseverance, and also the capacity for improvement possessed by Indian tobacco:—"The factory is now turning out 500 lbs. a day of all classes, the greater part of which is black cavendish and honeydew, intended for sale to the army. The finer smoking mixtures are only turned out in quantities required to meet the more limited demand for refined tobaccos. . . . The machinery is capable of turning out 3,500lbs. a day as soon as a sufficient number of hands have been properly trained. . .

"Hitherto no Indian tobacco has realized any valuation approaching that of American tobacco. Taking the average of the American leaf, which is called shipping tobacco, as 5*d.* to 6*d.* a lb., higher classes of bright leaf, from Virginia, realise as much as 7*d.* to 13*d.* a lb. : the price of Indian tobacco has generally been from 1*d.* to 2*d.* a lb. But for the last year, an excessive stock and a new tax have driven down the market for American tobacco to exceptionally low rates, and the low-priced shipping leaf did not fetch more than 4*d.* to 5*d.* It was at this time that the leaf raised in 1877 (the year of drought) reached England. The amount sent was 15,000lbs. of Poosah leaf.

"The consignment was, however, packed in rather damp order, and contained a quantity of moisture which caused it to be assessed under the highest rate of the new tariff, which imposes 3/10*d.* duty on tobacco with moisture over 10 per cent., against 3/6*d.*, on tobacco with moisture under 10 per cent. This being a new regulation, passed after the shipment of consignment, made a considerable difference in the value of the tobacco, a difference estimated indeed by the English broker at 1*d.* per lb. Had the regulation been promulgated earlier, the loss could have been easily avoided. The price obtained was 3½*d.*, which would have been 4½*d.* had the tobacco been dryer, and the sale has been followed by a telegram from England to prepare for despatch of large shipments.

The market was more than 25 per cent. below its normal rate, and it is now fast improving, partly in consequence of a bad season in America.

"The high price, however, realised both for the best samples of the 1876 and 1877 crops, indicate very strongly that an Indian leaf can be turned out of equal quality to the best shipping tobacco from America. A tierce of strips from the 1876-77 crop from Ghazipore sold for 7*d.* a lb., and the greater part of the rest for 5*d.* or more, while a portion of the Poosah leaf of 1877-78 was actually valued at 5*d.*, when the market was, as already observed, 25 per cent. below normal rates. These facts seem sufficient to guarantee future success, since year by year the quantity of the higher classes can be largely increased and the greater portion of the crop brought to the same higher level. The chief point to be ascertained was *whether a sufficiently high level could be attained at all. It has been attained.* The cured leaf of 1878 is, indeed very much superior to any which has been hitherto turned out, especially that from Ghazipore. In all, 165,000 lbs. are now lying in 'bulk' in the curing-houses, of which from 50,000 to 100,000lbs. will be shipped round the Cape at the end of the rains, and must for the reasons already given, realise much higher prices than the consignment of 1877.

"A new market is not unlikely to open in France. The French Government have already asked for and received samples, which they have pronounced to be better than any they have had from India before, and they have shown their practical appreciation of its quality by asking for a larger consignment for trial, to the extent of 1,000 or 1,500 lbs. . . .

"It is necessary to explain why, if the principal object in view is competition with American leaf, manufacture of smoking tobacco for Indian consumption has occupied so large attention in the operations of the year. The reason is simple. The Indian market, though small, pays far more handsome profits than the English market. The price paid for reasonably good American manufactured tobacco in this country ranges from one to three rupees a lb. The Ghazipore and Poosah tobacco is sold at just one-half that price, at a much higher profit than can be obtained by sending cured leaf to England.

"The success which is being obtained in Indian sales is as satisfactory as it could possibly be. Buyers are numerous in all parts of India, and in the majority of cases a first order has been followed by others from the same purchaser. Tradesmen are beginning to make large wholesale demands, and numerous testimonials have been received to the excellent quality of the tobacco. . . .

"While, therefore, India *cured* leaf can find a sale in the English market at prices which will enable it to compete there with American *cured* leaf, Indian *manufactured* leaf is proved to compete successfully with American *manufactured* leaf in India itself, with a fair prospect of success in a similar competition in the colonies.

"I refrain purposely from giving exact details of the cost of preparing cured and manufactured tobacco, but I may state in general terms that a price of 4*d.* a lb. for cured leaf in England, and from 6 annas to 10 annas for manufactured leaf in India will secure sufficient or even handsome profits. Now the Americans do not hesitate to say that they can raise the price of the cured leaf to more than 5*d.* a lb. in years of normal rates, while experience has proved that they can readily sell manufactured tobacco at wholesale rates of 8 annas to 1 rupee a lb., which prices, whether for cured leaf in England or for manufactured leaf in India, will more than command success. The opening for profits will perhaps be better understood if it is explained that 1*d.* a lb. represents an asset of about £5 an acre. . . .

"The one great advantage which India has over America is the cheapness of labour. It is now proved that the leaf is, for all practical purposes, as good as the American leaf, and there is hardly any doubt that the high price of labour must handicap America which cannot afford to send home leaf at the price at which India can sell. The prices of this year in England actually caused loss to many American exporters and growers, whereas they never reached a limit which does not leave a margin of profit to India."

THE

INDIAN AGRICULTURIST.

A MONTHLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. V.] CALCUTTA : MONDAY, 1st NOVEMBER, 1880. [No. 11.

NOTICE.

The INDIAN AGRICULTURIST *will be supplied to all Schools and Missionaries in India at half price.*

R. KNIGHT.
Proprietor.

Calcutta, 1st Feb. 1876.

CONTENTS.

NOTICES TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

CORRESPONDENCE.

NOTICES TO CORRESPONDENTS.

SUGGESTION.—Declined with thanks.

BASTALE.—Unauthenticated.

TREE MALLOW.—T. T. L. writes:—"I will be glad to receive some seeds of the Tree Mallow with a view of cultivating, and will be glad to note and send you results." This refers to a letter in our last number, headed "A Substitute for the Poppy." We have accordingly sent our correspondent a small packet of the seeds.—ED., *I. A.*

THE "KIKAR" TREE.

TO THE EDITOR.

SIR,—In an article on *reh*, at the top of page 282 in the October *Indian Agriculturist*, a tree is mentioned, the name of which is *Kikar.* I judge this to be a local term. Can you inform me what is the botanical name of the tree,, and also let me know where I can procure some seed for trial on similar land here in Southern India.

W. S. HOWLAND.

Mandapasalai, South India.

NOTE.—The *Kikar* of India is the *Acacia Leucophlœa*, a very thorny white barked tree found in most parts of the country. The timber, in characteristics, much resembles that of the *Acacia Arabica*, and is used for the same purposes, viz.: spokes, naves, and felloes of wheels, ploughshares, and tent pegs. The seed of the *Kikar* can be obtained at any place where the tree grows, which is principally in the N.-W. P., and the Punjab, but we do not suppose any one keeps it for sale. Our correspondent must try and get some from a friend in the N.-W. P. or from the Curator of the Lucknow Botanical Gardens, or those of Saharunpore.—ED., *I. A.*

MANGOES: INFORMATION WANTED.

TO THE EDITOR.

SIR,—Is the Madras Presidency a good mango-producing country? by which I mean, is it like the N.-W. P. and Oudh, and is mango graft growing remunerative in Bangalore. I should also like to know if the natives of the benighted Presidency have advanced so far as to name the different kinds of mangoes.

LUNGRA.

NOTE.—Perhaps some of our readers well acquainted with the climate and *flora* of the Madras Presidency will afford the information.—ED., *I. A.*

AVERAGE YIELD OF COCOANUT PALMS.

TO THE EDITOR.

SIR,—With reference to the letter in your last number, extracted from the *Ceylon Observer*, on the subject of the yield of the cocoanut palm, I have inquired of several ryots owning cocoanut topes in this division, and they all tell me that a cocoanut palm in full bearing yields from 60 to 100 nuts per annum. Ryots are generally accurate in their statements about such matters. Are they wrong here? Some two months before I saw the letter referred to, I inquired about the yield of these trees, of the owner of a large tope in the Madaksira Taluq of the division, and he told me that it was not uncommon for a tree to bear 140 nuts per annum. I should be glad to learn if the tree any where else is said to bear so prolifically.

M. HAMMIELL.

Camp, Pennaconda, Bellary District, 18th Oct. 1880.

NOTE.—We do not for a moment question the accuracy of the information given by the *Observer* as to the average yield (25 to 30 nuts per annum) of the cocoanut palm in Ceylon; we can only say that it is rather small and certainly below the average obtained in other parts. For the whole of India we should think that 40 nuts is a fair figure for an *average.* But of course the yield varies considerably in different parts and under different conditions. In some districts, for instance, trees in full bearing yield about 100 nuts (in clusters of about a dozen each) per annum, while in other places even more than this; so that we see no reason why our correspondent should doubt the truth of the ryots' assertions.—ED., *I. A.*

OATS: INFORMATION WANTED.

TO THE EDITOR.

SIR,—I would feel obliged for some information regarding the cultivation of oats.—What description of seed is suitable to India; the kind of soil best adapted; the best period for sowing; whether oats should be irrigated or not; how sown, and whether it will bear transplanting; and any other hints that may suggest themselves, that would be useful.

I believe that oats are grown with much success in the vicinity of Poona, and from a small experiment tried on my farm near Bangalore, I am inclined to think that a good crop could be raised. Before, however, venturing extensively in oat cultivation, I should like to have the advice and opinion of those who have succeeded with it.

T. T. L.

Bangalore, 23rd October 1880.

NOTE.—We insert our correspondent's letter with pleasure in the hope that it may catch the eye of some philanthropic friend who, with plenty of time at his disposal, and well acquainted with the subject, will good-naturedly sit down and indite a pamphlet on Oats for the special edification of T. T. L. But, joking apart, we wonder our correspondent does not see the absurdity (and some other of our subscribers might take the hint) of putting a host of questions, covering so vast an area as the above, on a special subject, and which therefore necessarily requires special information. To reply to his questions in a manner to be of any use to T. T. L., would occupy *pages* of the *Agriculturist*. For indeed some of the queries are of such an elementary nature that it would be necessary for us to enter into a detailed exposition of the whole subject. We would recommend our correspondent to provide himself at once with a book on the subject, of which there are plenty to be had.—ED., *I. A.*

"HANDLING" COFFEE.

TO THE EDITOR.

SIR,—Will any of your numerous readers be so kind as to answer the following questions:—

In what manner does "handling," as it is termed by coffee planters, affect the produce.

By handling is meant by the Neilgherri planter, I believe, the breaking off of small shoots which make their appearance after the plant is in blossom. It is my theory that Nature provides at certain seasons a fruit as well as a leaf-bearing sap, and while the former is making its way up, the leaf sap is in abeyance until the flowers have formed, when the sap unites and each performs its own functions. If this theory be correct, there can be only a limited amount of fruit or sugar sap as I shall call it, which it is to be supposed depends on the moisture in the soil or atmospheric changes. Now, taking such for granted, I hold that after the flowers have formed, the removal of shoots producing leaf can in no way tend to develop the fruit, or add to its yield, but, on the contrary, it must weaken and sicken the plant if the leaves are, as is supposed, the lungs, helping to sustain life. The removal of a portion of the fruit, any gardener will tell you, tends to increase the size of what is allowed to remain on the tree, but in treating coffee in this manner, the planter would consider he would be reducing his prospects. To me it appears that this handling is an utter mistake, and that what is alone necessary is moisture and nourishment in the way of manure at the proper season, *i.e.*, after the flowers make their appearance; but being a new hand at coffee-planting, I seek for information.

E. A. C.

NOTE.—We so far agree with our correspondent in that the removal of the young shoots cannot fail to be deleterious to the future prospects of the fruit. We do not think, however, it will affect the crop of berries *then* on the plant. It will affect the future, because from these young shoots the new wood and crop are matured. If the theory of two saps were correct there would be no use in tea planters nipping off the flowers to increase the coming leap crop.—ED., *I. A.*

RAILWAY SLEEPERS.

TO THE EDITOR.

SIR,—The Deputy Conservator in charge of the Chenab Division, Punjab Forest Department, has lately advertized for sawyers to proceed to the forests in the hills, next year, to cut up *deodar* logs into sleepers.

This is a good idea in its way, and one which, if properly worked, will prove very profitable to the Forest Department. But have any facts connected with the due seasoning of the timber, been taken into consideration?

Before proceeding any further in the matter, it would be advisable for the Conservator of the Punjab forests to spend two or three days at any one of the sleeper depôts on the Punjab rivers, belonging to native merchants, and examine into the reasons of the inferior quality of the sleepers lately brought down from the hill or now being brought down from these.

He will find the chief cause to be that the trees are felled and converted into sleepers while the wood is perfectly unseasoned; they are then thrown into the river where the outside portions swell, in an unnatural manner, (it cannot be called seasoning as the wood is too green and fresh to allow of the water penetrating in an equable manner; only the surface becomes soaked), and as they alternately float about the river and lie on the rocks and islands in the water—according as the river rises or falls, and carries them off or strands them on any point they may catch on—they crack and split to such an extraordinary degree, that the greater number of them are rendered useless.

The results of careful and laborious examinations of several thousands of sleepers, supplied by native timber merchants, are, that from *fifty to sixty per cent.* of their sleepers are useless for the purposes of a main line of railway, where there is heavy and fast traffic; of the rejections a portion of them will prove useful in sidings, but for nothing else in the way of sleepers.

The cure, of course, is to allow the timber to be properly seasoned before converting it into sleepers, *i.e.*:—

1. Fell your trees and let them lie in the forests for *two years*.
2. The *third year*, clear the branches and get rid of the bark.
3. The *fourth year*, convert into sleepers and launch them into the river, but not immediately; allow the sleepers a month or two to lie in the forests to complete their seasoning.
4. Beware of the sap-wood: cut your sleepers only from the heart-wood within that outer ring.

In this way *deodar* sleepers could be obtained capable of lasting from 16 to 20 years, if not longer; it is difficult to fix the period of their duration under the new method of proceeding alluded to, as it is believed that up to the present no properly seasoned *deodar* sleepers have ever been used by the different railway companies.

Mind, a sleeper may be five years old before it is offered to a railway company and made use of on the railway. Yet that does not mean to say that the sleeper is of seasoned wood; it may have been felled and converted in its first year. It would occupy two years to reach the depôt in the plains, and it might remain there two years before it was sold; result being that it is quite unseasoned and is gradually passing into a state of natural decay before it is even laid down under the rails.

The large sleeper depôt at Wazirabad belonging to native merchants is a most instructive one, and well illustrates the manner in which the gifts of Providence can be abused when left to the care of inexperienced and money-grubbing individuals. The sleepers there, come from the territory of the Maharajah of Cashmere, and the waste is dreadful to behold; from 50 to 60 per cent. of the sleepers are unuseable, as already explained. Of course the Maharajah has no supervision over his forests: the trees are sold to the highest bidder, and the timber merchant is only anxious to turn over his capital as soon as he can, hence a plentiful supply of unseasoned *deodar* sleepers to the different railway companies and consequent frequent and large outlays for renewals at, comparatively speaking, short intervals.

FORESTER.

ABOUT PAPER FIBRES.

TO THE EDITOR.

SIR,—The article with the above heading in your journal of September, refers apparently to the Blue-book Memorandum on "Materials in India suitable for the manufacture of Paper" compiled by Mr. Liotard of the Agricultural Department, and published by the Indian Government in Calcutta.

I think you would do good service by reviewing this publication *in extenso*, seeing that the cultivation and treatment of raw fibrous material is an important division of agriculture, to which subject your journal is specially devoted; meanwhile I transmit you by this mail our Paper Trade Monthly journal, in which you will find abstract of that portion of the said publication relating to "*Bamboo, as a material for Paper-making*," for the discussion of which question you have been good enough to allow me considerable space during the past two years.

The abstracts from reports of Forest Conservators and Collectors in various districts in India in Mr. Liotard's compilation enumerate an enormous number of fibrous plants from which no doubt paper of varying quality could be manufactured, inasmuch as from nearly every vegetable fibre paper of one description or other can be produced. The commercial and practical issues, however, are not merely whether paper can be made from any given fibre, but of what quality, and more, especially at what cost—the latter after all being the crucial point or question, as it is useless to discuss the question of quality if cost is prohibitive.

I venture as a practical paper manufacturer fairly conversant, not only theoretically, but practically, with nearly all the fibres enumerated in the Government Memorandum, (having indeed experimented upon most of them,) to assert, that not one-third, I almost venture to say not one-fourth of those referred to, can be *economically* reduced into a

merchantable condition suitable for English or European requirements. I mean to convey my conviction, and thus throw out a warning note to those who may be intending to experimentalise, but who are probably unacquainted with the technical requirements of the paper trade, that practically and commercially speaking—that is to say *profitably*, taking into consideration the cost of cultivation, or in the case of a purely wild plant, the cost of collection, the mechanical treatment, or other necessary manipulation, and the resulting yield or produce of fibre reduced to such a condition as to make it a saleable article to the paper-maker, considering also the cost of freight and transport from a country so remote as India to Europe—taking all this into consideration, I say that few or very few of the fibrous substances enumerated can be *profitably* utilised as articles of commerce.

The object, however, of this Government Memorandum is most laudable, as there can be no doubt that India teems with raw fibrous plants, suitable for textile manufactures as well as for paper-making. No doubt also that a fresh and extended supply of paper-making material either as a pure raw fibre, or the tow or waste from any fibre prepared for textile purposes, or semi-manufactured, or reduced to a rough stock, is a great desideratum for England, seeing that we are now mainly dependent on foreign countries for our chief raw material *esparto* or *alfa*; the imports of which you will observe from the Board of Trade returns (published in our Trade Journal) amounted to upwards of 120,000 tons in the first 8 months of the current year.

Esparto, however, is becoming both scarce and dear while deteriorating in quality, and such is the demand for paper-making material both in England and the continent, as well as the United States, that a variety of articles lower priced than *esparto* enter largely into consumption; notably wood pulp, both chemically and mechanically prepared, straw also, jute ends or butts, and gunny bagging, flax and hemp waste, &c., &c., so that any new material that will minister to the requirements of our trade will be gladly welcomed.

It will be obvious, however, that to command a market, any new fibre or fibrous material must be at least as good, or better in quality, and as cheap, or cheaper, than those now in use, and as *esparto* now forms the main staple of our paper trade, any fresh material must favorably compare with it to ensure its sale.

Alfa or African *esparto* now realises from £5-15 to £7-10, or £8 per ton; and Spanish from £10 to £10-15. It is generally understood in the trade that 2 tons of *esparto* are required for each 1 ton of paper.

Rags of course still enter largely, as they always will do, into the manufacture of paper, but rags range very wide with regard to both price and quality,—from £8 to £35 per ton, or even more, for the highest classes,—and are chiefly employed for the superior grades of paper.

What is really required in a new raw fibre or that fibre in a semi-prepared condition as "stock," is that it shall favorably compare at least with *esparto* grass, in cost, and be if possible superior in quality. For such a material the demand and sale would, practically speaking be illimitable.

I propose in a further letter to point out some few of the fibres enumerated in Mr. Liotard's Memorandum that offer a reasonable prospect of success. Meanwhile, I remain yours faithfully

THOS. ROUTLEDGE.

Claxheugh, 30th September 1880.

INDIGO CULTIVATION.

TO THE EDITOR.

SIR,—Would you be kind enough to enlighten me on the following points:—

1. The soil best suited to indigo.
2. The best mode of cultivation, and the depth the soil should be turned up.
3. The best time (month) for sowing, especially in the N.-W. Provinces.
4. The quantity of seed to be sown per acre.
5. The best seed for the N.-W. Provinces.
6. The average yield of plant per acre, in Factory maunds.
   (*a.*) Nowda on first cutting.
   (*b.*) Khootie on second cutting.
7. The highest yield of plant ever known, in Factory maunds.
   (*a.*) Nowda.
   (*b.*) Khootie.
8. The quantity of plant, in Factory maunds, that should be steeped in a vat—per 100 C. ft. capacity.
   (*a.*) Nowda.
   (*b.*) Khootie.
9. Should the steeping vat be deep or shallow, and what is the proper depth for a steeping vat,
10. The average yield of dye per 100 Factory maunds of plant.
   (*a.*) Nowda.
   (*b*) Khootie.
11. The highest yield of dye per 100 Factory maunds of plant ever known.
   (*a.*) Nowda.
   (*b.*) Khootie.

I have just got an Indigo Factory, and would feel much obliged for any information on the above points.

It is a great pity that experienced Indigo Planters do not make use of the *Indian Agriculturist* for an interchange of ideas on indigo planting and manufacturing. I am certain papers on the subject would be of the greatest advantage to young hands like myself.

W.

12th October 1880.

NOTE.—There are plenty of books on indigo cultivation, and we would recommend our correspondent to get one. To answer his series of questions properly, would take up far more space and time than we can afford.—ED., *I. A.*

MR. GAMMIE ON CINCHONA CULTIVATION.

(*To the Editor of the Ceylon Observer.*)

DEAR SIR,—In a late issue, in writing of the scraping process of collecting cinchona bark, you suggest the probable difficulty of getting the brokers to take to the bark in the new shape of short shavings so obtained. This appears to me, from late experience, to be a mistake, as smashed up *Ledgeriana* bark lately sent from the Bengal Government plantations sold quite as well, relatively, as did the long quill-shaped pieces. For convenience in packing, it was put through a bark mill so set as to break the bark up into pieces of an inch square or less, and in this form was shovelled into ordinary gunny bags, thus reducing the packing to the simplest possible shape. Bark for the manufacture of quinine must necessarily be sold on its inherent merits, and appearance can but little, if it all, influence the price. Of course "show" bark is quite another matter.

You mention that the experiment of reducing bark to powder before shipment was tried in Java, but failed. I suspect the best bark was not powdered, and that the powder sold quite as well as if the bark had been in an unpowdered state. At least this appears to me to be the commonsense view of the matter. Though I do not think that the appearance of the "scraped" bark will be against it in the market, I have very little hopes of the ultimate success of the scraping process in Northern India. It may answer well enough in the more favored climates of Java and Ceylon, and the process is well worth a trial. Trees scraped nine months ago in Sikkim do not appear to have suffered in health as yet, but the renewed bark has that corky appearance which you have referred to, and which I do not like any better than you do yourself. Nine months experience shows that the scraping can be done any month in the year. One month appears to be as good as any other. Where the scraping can be repeated frequently, as appears to be the case in Java, the process must be a most profitable one.

A good deal has been written of late in praise of grafting *Ledgeriana* on to *succirubra* stocks. We tried grafting cinchonas in Sikkim thirteen years ago, but though the grafts "took' readily and grew well for a year or so, their after growth compared so unfavorably with that of plants on their own roots that the process was abandoned. Formerly I was strongly of opinion that it was of the greatest importance in forming plantation of *Ledgeriana* that plants of the known good kinds only should be put out, and had the temerity to take the senior editor of your paper to task for advocating a more venturesome policy. It was, I presume, in consequence of holding a similar opinion to mine, and the difficulty in getting cuttings of this species to root that induced the cinchona authorities in Java to adopt the grafting process for the preparation of *Ledgeriana*. But in the face of the late Bengal bark sales, I am not sure that our worthy editor's opinion was not the right one. Smashed up bark of the variety approaching *succirubra* in appearance, and which was pronounced on analysis to be our worst kind, fetched the fair price of 2*s*. to 2*s*. 10*d*. a pound. This, it is true, is a poor return compared with 7*s*. 6*d*., which bark of the better sorts, in the same shape, fetched, but as it is a much more robust growing plant, the actual difference in money value is not so great. I do not mean for a moment to advocate the careless selection of seed—quite the reverse, but merely wish to point out that probably you were right in thinking there would not be much risk incurred in cultivating all the varieties raised from seed of true *Ledgeriana*. There were none of these *succirubra*-looking varieties among the plants raised from the seed collected by Ledger. At the worst, the large leaved varieties grow quite as fast and as big as *succirubra*, and the bark fetches about as good a price. In my opinion it will always pay better to cultivate a species robust in habit and yielding a fairly good bark than it will to

grow a shor, however rich in quinine, if of a weakly and uncertain habit. I have good hopes that the best Sikkim *Ledgeriana* will prove a good grower, exceedingly rich in quinine, and that—most important point of all—it will reproduce itself by seed almost as truly as *succirubra* does. Another year will settle these points. It seems to be generally overlooked when comparing the results yielded by the Sikkim *Ledgeriana* barks with those of Java that our bark was analysed when only four and five years old—even at that early age it yielded up to 7 per cent. of crystallized quinine.

The species yielding the Carthagena bark appears likely to be a formidable rival to *succirubra* as far as rapidity of growth and ease of propagation are concerned. But old cinchona planters in India and Ceylon will always have a warm corner in their affections for *succirubra*, and notwithstanding all that has been written against the extension of it, I believe it will yet be *the* cinchona to yield a cheap and efficient febrifuge, equal in appearance to sulphate of quinine, for the fever-stricken millions, and at the same time give a good return to the growers.

3rd September 1880. JAS. A. GAMMIE.

FROST ON COFFEE.

I.

(*To the Editor of the Ceylon Observer.*)

DEAR SIR,—I notice, in that able article* on frosts, by Messrs. J. M. Robertson & Co., what I suspect to be a flaw in the writer's philosophy. He is not very clear in showing how the cold could be greater on the upper branches than on the lower, and I surmise that if he tested it by a thermometer, he would find the reverse to be the case. The fact I believe is that it is not the "frosting" but the "thawing" that blackens the coffee leaves. When a man's nose gets "frosted" in cold climates, he suffers no permanent injury if the condition of the nose is ascertained in time, and it be rubbed with snow till circulation is restored. Otherwise it would decay and drop from his face.

So when potatoes are "frosted" at home, they are put into ice-cold water, and moved about till the frost is gradually removed and they are as good as ever. Otherwise they would be useless.

So when a gardener discovers in the early morning that the frost has nipped his plants, he covers them up from the sun till they have been gradually thawed.

So I fancy it is with the frosted coffee. The morning sun shining aslant, touches only the top branches, and so their leaves are blackened, while the lower ones thawing gradually, are all right. Is it not the case that many places liable to frost in accordance with the theory under notice do not suffer at all from the fact that the morning sun does not touch them?—Yours truly,

THAW.

Kandy, Sept. 14th, 1880.

* See Selections under "Coffee."—Ed., *I. A.*

II.

DEAR "OBSERVER,"—It seems "the Writer of the Memorandum" and I do not quite understand each other. Not being so intimately acquainted with coffee trees as some, I had an idea that the upper primaries would not shade *entirely* the ends of the lower primaries; but would be a sort of modification of the sucker and lower primary form described by J. M. R. & Co., and consequently the *ends* of the lower primaries, though free to radiate their heat into space, and to get colder than the upper from the descent of the cold air, would yet be shaded by the upper from the morning sun, and so escape injury. The matter seems deserving attention from this consideration that it would be easy to plant a row of trees, or leave a belt of jungle in a position to protect a flat from the first rays of the morning sun, while it would not be so easy to cover all the trees on the flat from frost.—Yours truly,

THAW.

WILL WHITE ANTS ATTACK LIVING TREES?

(*To the Editor of the Times of India.*)

SIR,—Your correspondent at Dharwar calls upon me to explain theoretically why white ants do not eat plants with vitality. It is a known popular error that white ants do eat plants with vitality, but naturalists differ in this. Sir E. Tennent states, what any one in this country must have noticed, that—"Termites rarely attack a living tree, and although their nests may be built against it, it continues to flourish not the less for their presence." Likewise Mr. Gosse in hi "Naturalist's Sojourn in Jamaica," states that Smeathman, who has very minutely described and illustrated the tribes of Termites, says, ey do not usually attack trees in a sound state. My own experience throughout the three presidencies of India concurs with the above. In the jungles of Wynaad I have seen trees covered with a coating of soil to the height of 20ft. from the ground, as if put on by the hand of man. Return to the same tree in the dry season, this will have all fallen off and left the tree without a speck of old decayed bark sufficient to prove to any close observer that it is only decaying and dead matter that is eaten by Termites.

As to the failure of your correspondent's blue gums, there might be many causes other than a knock with a tool. Plant life appears to me to be subject to as many ills as animal life suffers from. I have got a quantity of *Poinciana Regia* trees dying off just now, with what is popularly known as colar rot. I should be very much obliged if any of your numerous readers could tell me, through your columns, the reason why? I lost some 200 blue gums similarly last hot weather, and my *malee* persisted in saying they were destroyed by white ants. I had one of these *Poincianas* dug up immediately on its showing signs of drooping, more to convince a friend that the effects were not due to white ants, than from any curiosity on my own part; when I found the liber or inner bark of all the roots as well as the inner bark of the stem to about six inches above ground line, blackened of a glutinous consistency. Might it be that the roots were not capable of utilizing the large amount of elaborated sap the leaves have been returning to them, by being injured in any way or turned out of their natural channel, as I found the roots growing in a circle, in fact just as they had been confined by the pot two years ago before they were put into the ground. My observation leads me to this conclusion, as you will seldom see tree or plant self-sown die of colar rot.

GUZERAT.

Baroda, September 18.

WILL FARMING PAY?

(*To the Editor, of the Madras Times.*)

SIR,—Your correspondent, "Unconnected Traveller," appears to think that it is no use a European or Eurasian attempting to compete with the native in agricultural pursuits. I ask, has it been fully and regularly tried in these parts? And I reply that it has not. There have been instances—and probably one of these may have come under your correspondent's notice, and from which he has concluded that farming by Europeans or Eurasians will not pay—when Europeans have taken up lands and professed to farm, but in reality left all matter pertaining thereto to natives, who, of course, feathered their own nests, and so farming proves a failure. But I have only known of one instance when a European resided on his own farm, and superintended operations personally, and he made it pay over and over again. I can quote a dozen instances of how failure was brought about in the way I allude to—*Absenteeism*. Like all other matters of business or speculation, the farmer must be on the spot and not trust to a middleman.

Only lately I came across an account in the Bombay papers of a couple of Eurasians, who had taken to farming near Ahmedabad, making it pay; they, it was said, *lived on their farm*. Again in the *Delhi Gazette* I read of the great success which crowned the efforts of two Europeans who went into farming, principally rice and sugarcane, in some part of the North-Western Provinces, *they made their home on their land*. I would have asked, *en passant*, whether if a coffee planter was to live in Madras or Bangalore and leave his estate to a native would he get the same outturn of crop as if he lived on the land? Herein lies the secret—to be a successful farmer in India or elsewhere, there must be close application to details, and to ensure this a man must *live on his land*.

Then, again, your correspondent asserts that "it is very doubtful if the land would yield any more than it does at present." There is no foundation for this statement. It has been amply and fully proved that land can be improved by careful ploughing and manuring to such an extent as to make it yield double and treble, aye and four-fold, the crop such land did under the wretched cultivation of the native ryot. Such men as Mr. Harman, at the Government Farm, Bangalore, Mr. Cameron, F.L.S., of the Lal Bagh, the Superintendent of the Sydapett Farm, and others who have made experiments with cereals on a large scale, will tell you what land in India is capable of. The former gentleman made some excellent trials of *raggi* grain, cholum, &c., which proved, by improved methods of ploughing combined with proper manuring, that it was possible to get such bumper crops as the native never dreams or hopes to get. Your correspondent ought to read the *Indian Agriculturist*, and note the progress that is being made in the development of improved agriculture in India, and I maintain that, with good subsoil ploughing, and manuring, a stout heart and ready hand, and above all a residence on his own land will conduce to farming paying handsomely.

I have my own ideas how farming in connection with the Eurasian Association would provide for a large number of men and women not

afraid of work, and give them a good livelihood, but those who have the direction of affairs do not, apparently, want the advice or experience of an outsider; so I won't trouble you, but I should like to say, before concluding, that by way of convincing your correspondent that "land will yield more than it does at present." I shall be glad to show him a field of *raggi* on my farm treated to good ploughing and proper manuring, which he can compare with fields contiguous to mine, but cultivated by natives, and if he does not admit that mine is the better of the two by fifty per cent., then I am a Dutchman, and if he waits till the grain is ripe, I will cut yard for yard with the other fields, and he will see that my outturn is one-and-a-half to one of the other.

Bangalore, 16th September. L.

NATIVE TOBACCO CULTIVATION IN CEYLON.

(To the Editor of the Ceylon Times.)

SIR,—In the Northern Province the approximate cost of raising tobacco shews a profit of about Rs. 275 an acre upon the seven months' cultivation. It would be comparatively easy to raise two crops in the year, the paucity of rains rendering the crop, entirely dependent on irrigation. The waste of time in preparing the ground is quite unnecessary, as a matter of fact more than half the value of the cattle manure is evaporated by its being left to bake in the sun.

The patches cultivated are very small, and are measured in Lachams, 17 being the equivalent of an acre English.

The details are, for say—5 Lachams.

Keep cattle on the ground for 3 months, from September.

In December throw in the manure with	10 coolies at 37 cents...	3·70	
Do.	Plough twice at a rupee each ploughing ...	2·00	
Do.	Plant and shade the plants	1·87	
Watering	2 coolies each 30 cents. for 120 days	72·00	
		79·57	

These men suffice to keep off blossoms, weed, and pluck, watering being carried on from 5 to 7 A.M., and 4 to 6 P.M. only.

For crop 5 Lachams contain 1,500 plants each 10 leaves.			
3,000 top leaves each at 4 cents.	120·00		
12,000 inferior leaves each at 1 cent.	120·00	240·00	
15,000		160·43	

No allowance is made for superintendence, rent, or curing; on the other hand Rs. 10 per thousand buys the commonest description of leaf produced, Cuba or Havana sorts being valued at four times this rate.

A. C. H.

WEST INDIAN YAM CULTIVATION, &c.

(To the Editor of the Ceylon Observer.)

SIR,—In an interesting review of the Quarterly Statistical Report on Jamaica, in your issue of the 27th instant, you make the following query, with reference to the splendid yam crop gathered in that island, viz.:—"*Why has the West Indian yam never established itself in Ceylon?—is our soil too poor?*" If you will permit me, I think I will be able to prove that these roots succeed quite as well in Ceylon as in any of the W. Indian islands,—if fair play is only given them. True, they delight in a good virgin soil, and do come to great perfection in the wonderful volcanic formations of the W. Indies: still I feel quite sure that our fine climate, and distributed rainfall, fully compensate for the inferiority of our soil. I have seen as good a return here, as ever I did in the West, and it is not in the poverty of our soil we have to look for any want of success (if indeed fair trials have been made), but in very different causes. The first of these is to be found in the apathy and want of enterprise on the part of the rural population; the other in the abundance of four-footed pests, which haunt the jungles and clearings, but which might be got rid of, were more energy and perseverance displayed. Mr. *Hystrix leucura* (the porcupine) has much to account for, but it is very hard to bring him to account, gifted as he is by nature, with admirable weapons of defence —a keen nose and formidable spines. The *bandicoot rat*, too, is not slow in asserting his right to a full share of the plunder to be had, and the wild hog, in his midnight rambles, knows no bounds to his wholesale depredations. These marauders are, so to speak, the principal *natural restraints* to the propagation of all edible roots, and are purely nocturnal in their habits, sleeping during the day under rocks, tree roots, and in other retreats, and sallying forth at night to prosecute their deeds of darkness. In most of the West India islands, these enemies to the cultivation of ground provisions are represented by only one interesting little rodent—the *aguti*. It is of the size and has all the habits of our little *mimima* deer, and is closely allied to the *guinea pig family*. It is easily kept within bounds, and in most situations I do not think there would be much difficulty in guarding against the ravages of our Ceylon pests.

I had a good deal of experience in the cultivation of these fine roots, and other products, in the West Indies, and I have now got a small nursery in Kandy, containing the finest varieties of *W. Ind. yams*, *Eddoes*, true *plantains*, and many other introductions. A visit to the nursery would I think satisfy any one that these handsome creepers thrive and yield remarkably well in our climate, and that too with little expense or trouble. The present crop will not be ripe for sometime, but I am now booking orders for plants or sets of the various yams, &c., and I shall furnish full instructions as to cultivation on their delivery.

I do not hesitate to say that these roots, if generally cultivated, would be a great boon to the Island. They are infinitely superior to the native yams, and very much nicer and more nutritious than the ordinary waxy potatoes sold in our markets. The *cush-cush*, *guinea*, and *water yams* were in the W. Indies generally preferred to English or American potatoes, and I believe the *cush-cush* yam to be the most delicate and palatable of all ground roots.

A. WHYTE.

The Kandy Nursery, 28th Aug. 1880.

GUTTA-PERCHA.

(To the Editor of the Ceylon Times.)

SIR,—Some time since a letter appeared in your journal on the subject of gutta-percha. As I have also taken some interest in this product, I am now enabled to send you the following few remarks on its cultivation, &c. The gutta taban, or tuban, trees are found in Sumatra, Johore, Java, Borneo, and in Singapore, extending over a tract of country from 6° to 10° N. lat. to 10°S. lat., and from 100° to 120°E. long.

The tree (tuban) has a straight stem from 60 to 30 feet growing to a height of 100 to 120 feet, and when fully grown is from 2 to 3 feet in diameter. The wood of the tree is soft, fibrous, and spongy, of a pale yellow, and marked by black lines consisting of reservoirs filled with the gum. The yield of a large and full grown tree is sometimes 23 cattys or 17¼ lbs. It is generally estimated that 10 full grown trees will yield 1 picul of gutta-percha or 133⅓lbs. The pure gutta-percha is worth some 2*s*.6*d* to 3*s*, 6*d* per lb. The old and destructive method of collection was to fell the tree and to ring it with an axe at intervals of 3 to 18 inches, the milk being collected in cocoanut husks, &c., and boiled to draw off the water. The soil most suited to the Gutta taban is precisely such as we have in Ceylon, the tree thrives well on naturally well drained hill-sides and in a free soil, and at a considerable elevation. The great drawback to its cultivation is, that it is a very slow grower, taking nearly thirty years to arrive at its full growth, when it is about three feet in circumference, at a height of three feet from the ground. The seeds readily germinate, and the best method of putting out the plant is in bamboo pots, as the tap-root is long, and impatient of any injury Gutta-percha is entirely distinct from caoutchouc. It reaches the English market from the Straits in three different preparations; the first being boiled milk, of pink color, hard and tough and mixed with bark and other natural impurity: the second, gutta-muntah, being a preparation of gutta reboiled up with cocoanut oil and inferior juices (such as that of the mudar tree, which grows commonly in Ceylon;) and the third is the crude gutta-percha, being simply the milk, hardened without any process whatever. The gutta-percha of commerce consists of pure gutta and 15 per cent. of a soft resin mixed with it—the resin has the simple chemical action of absorbing oxygen, without which property, light, such as the sun's rays, would render the gutta brittle, friable, and resinous; it is known that in submarine cables line gutta-percha does not sensibly decay, being protected from the light.

PIONEER.

THE METAL OF THE FUTURE.

(To the Editor of the Public Opinion.)

SIR,—Your last issue contains a paragraph on "Cheap Aluminium," in which you justly remark that "the importance of a cheap method of producing aluminium can scarcely be over-estimated. As a metal it is probably the most abundant in the crust of the earth." The aspect of the question is indeed so vast that it is almost impossible to realise the

revolution which would be brought about by the invention of any cheap and efficient method of reducing the metal from its ores on a large scale. It is no exaggeration to say that to whatever place you go, from the equator to the poles, you will find some compound of aluminium in abundance on the surface. It enters into the composition of our granite hills, it is contained in every species of clay, it is a most important constituent of all fertile soils. In the form of rubies and sapphires it sparkles in the regal diadem; and in that of a clay pipe it solaces the humblest workman.

With regard to its possible utility, I may point out that bulk for bulk, it is only one-third as heavy as iron; it is not acted upon by air, water, or sulphur (in which last particular it excels the noblest metals—gold, silver, and platinum); it is readily malleable, and may be drawn into fine wire; it is as sonorous as silver for bells and musical instruments; it is one of the very best conductors for electricity, in which capacity it again rivals pure silver; it is excellently adapted for casting in moulds, and after rolling or hammering becomes nearly as hard as iron. Its most important property is, perhaps, its lightness, and if ever the problem of aërial navigation is to be accomplished, it will be by means of machinery made of aluminium. If used for railway rolling stock, it would reduce the weight of trains by one-half, and would be equally applicable to bicycles and artillery. Its incorrodibility points to it as the best material for the sheathing of ships, for all submarine works and machinery, and for gas and water pipes. Lastly its high electrical conductivity, together with its lightness and resistance of chemical deterioration, would render it invaluable for telegraph wires and cables.

It is possible that the iron age is destined to be succeeded in turn by an aluminium age, and if so it will assuredly be an age of unprecedented progress and advancement in arts, manufactures, sciences, and civilisation.

Yours obediently,
SAPPHIRE.

The Indian Agriculturist.

CALCUTTA, NOVEMBER 1, 1880.

TENANT RIGHT IN INDIA.

AN instructive comparison might be drawn between the agricultural policy of Ireland and of Upper India during the past ten years. In both countries the conviction has been slowly gaining ground that it is a mistake to have divided interests in the land when a whole population is irretrievably committed to agricultural pursuits. Irish tenants, not content with the amelioration of their condition effected by the Land Act, are agitating now for the total abolition of rent; and though the object is unattainable, there is every prospect that something like fixity of rent and tenure will actually be won. The Indian peasantry are less obtrusive of their claims. It is a beneficent Government that watches over them, and interposes in their behalf when they seem to need protection. Land legislation since the mutiny has followed one unvarying tenor in favour of the tenant; and at the present moment we see no less than three measures on the Council table, each of which is an attempt to establish between landlord and tenant some *modus vivendi* which shall be more tolerable for the latter. There is the Bengal Rent Commission, there is the amendment of the Rent Law of the North-Western Provinces, and, most significant of all, there is the Tenancy Bill for the Central Provinces. Besides these, special inquiry is making into the condition of the tenantry of Behar, and Burmah is being settled on principles which ignore landlordism altogether. It is a wonder that this great Indian movement, the more remarkable because it is strictly official, has not been turned to account by any of the leading Irish agitators. They might draw from State papers most cogent arguments for their cause. India, indeed, is occasionally quoted by these gentlemen, but for other purposes. It serves them as an example of the blighting influence of English tyranny. At one of the Land League meetings, not long ago, the audience were gravely informed that by reason of the Arms Act, wild beasts had so increased against the disarmed population that a tract of country 200,000 square miles in extent had been deserted by its inhabitants, and become the haunt of the tiger and the cobra. This statement seems to have been made in perfect good faith. The speaker was a Roman Catholic priest, and ought to have known geography better. But the fact that such a statement could be made, and could pass unchallenged, serves as a good illustration of the huge ignorance of Indian affairs which prevails at home. The Irish tenantry are heated with these vain fables, while nobody points out to them that their Indian brethren are already obtaining those concessions, are already becoming invested with those privileges, which the incessant stress and clamour of the Land League have hitherto been unable to extort from the English Parliament.

The Central Provinces Tenancy Bill contains provisions which might be taken as guides towards a solution of the Irish land question. It professes to improve the tenant's position in respect of four points,—namely, (1) sufficiency of notice before ejectment, (2) compensation for improvement, (3) facility of acquiring occupancy right, (4) security against harassing enhancements of rent. The first two points are of comparatively minor importance, and have been dealt with by recent agricultural legislation in England, after a fashion which, if not wholly satisfactory, will at any rate do well enough for the present. But occupancy right and fixity of rent are precisely the demands of the Irish cottier; and it will be interesting to consider for a moment how similar demands have been met by the Indian legislature for the ryot of the Central Provinces. In the first place, a right of occupancy can be acquired (if the Bill becomes law) by cultivation of any land in the village for five years, provided that the tenant has been able to get on without help from his landlord for the last three years of the five. It is not necessary that the tenant's holding should be the same throughout the five years, but merely that the lands cultivated, though they should vary every year, shall lie within the boundaries of the same village. The right of occupancy thus acquired will not indeed be commensurate with the full right of occupancy acquired by twelve years' cultivation, but it will protect the tenant against ejectment, and thus enable him to complete the further term of seven years, necessary for the conversion of this inchoate right into the perfect occupancy status. If the tenant dies in the meantime, his inchoate right dies with him; it is not, like the full right, transmissible to his heirs. There were those who proposed, in framing the Bill, that the term for the acquisition of the full right should be reduced from twelve to five years; but this, it appears, was classed among the 'heroic remedies,' which were especially deprecated by Mr. Grant in bringing the Bill before Council. Toned down as they are, the provisions regarding inchoate occupancy right have yet to stand the ordeal of severe criticism directed by able hands. There is perhaps no more capable revenue officer in India at the present moment than Mr. C. H. T. Crosthwaite; and he has thrown all the weight of his ability and experience into the cause of the landlords in this matter. It seems a pity that the cause should be able to boast such a champion. That recent legislation, in seeking to protect the tenant, has made itself responsible for much ill-will between him and his landlord, no man who has paid the slightest attention to the land question will be prepared to deny. It is easy to urge that further effort in the same direction will only be attended with similar consequences in an exaggerated form. There is plenty of room for forcible writing on the subject; there are abundant materials for example and illustration. It can be proved incontestably that the present rule of twelve years has set the landlords on the watch to prevent occupancy right by timely ejectment, and to break it down on the first occurrence of arrears. But what is the alternative? If occupancy right be withheld, there is no alternative but the complete subjection of the tenantry to the landlord, with results such as official reports describe in Behar. It is no answer to allege the admirable relations existing between the parties thirty years ago. The India of thirty years ago is not the India of to-day, and in the absence of the circumstances which fostered those old relations, it is vain to expect that questions between landlord and tenant will settle themselves, if left to themselves, without injustice to the weaker party, that is, to the tenant. In former days, land was plenty and labourers were few; tenants were in demand, they could make their own terms, they could appeal to customary law not yet outworn, they were needed by the landlord as allies against unscrupulous superiors. The landlord himself was a new creation, a being called into existence by mistake, as yet imperfectly acquainted with his powers, and afraid to exercise them. But this happy state of things could not last for ever. Apart from all legislation, the

mere increase of population must gradually have reduced the tenant from the position of a man sought after, to that of a suitor and a dependant. The law has sought to prevent his dependence from sinking to a point not far removed from serfage. It has given him rights, the practical value of which can best be tested by the keenness with which he battles for them ; and if his claims excite the enmity of the landlord, and our Courts resound with the clamour of both parties, surely even this is better than that the law should hand over the tenants, " like dumb, driven cattle," to suffer injustice without the power of complaint.

The enhancement of rent is intimately connected with the question of occupancy right. In the North-Western Province, the landlord must prove that the occupancy tenant's rent which he seeks to enhance, is below the average rent payable in the neighbourhood for that class of land. He can also claim to enhance rent on the ground that the value or the quantity of the produce has increased. By the new law for the Central Provinces, only the two latter reasons can be alleged in support of a claim to enhancement. This is a fact of the greatest importance. It abolishes the competitive theory of rents, at a stroke. It is the nearest move yet made towards that consummation which some of our ablest settlement officers have so strenuously recommended—the fixation of rents, as well as revenue, for the whole term of settlement. Under the North-Western Provinces rule, the landlord can virtually say to his occupancy tenant. 'Your rent is below the level to which rents in villages A, B, and C, have been raised by competition, and if you do not consent to have it raised to that level I will call in the power of the law.' There is not a revenue officer in the North-Western Provinces who has not good reason to know the harassment and heart-burning caused by these proceedings to the whole agricultural interest. It is unfortunately necessary, in most cases, to lend the landlord the support of the law, for he has been assessed to revenue in anticipation of a rise of rents. But the settlement officer ought to have enhanced the rents himself, at the time of assessment, so as to get done with the business once for all. This is the plan proposed now for the Central Provinces. In the intervals between settlement, that is, during periods of thirty years, enhancement of rent will be claimable only on the rare and exceptional ground of increase in quantity or value of produce. In a word, the status of the Central Provinces tenant, if this Bill be passed without material modification, will be as nearly as possible that which the most advanced section of the English Liberal party are striving to obtain for the Irish cottier. In a speech at Liverpool, a month ago, Mr. Leonard Courtney propounded what he called a solution of the Irish question according to Irish notions, by an arrangement under which " the tenant should pay fixed rental to the landowners which should be varied only by agreement or by a public tribunal, at stated intervals, and that so long as he pays his fixed rental, he should have a permanent holding of the lands he cultivates." These words might have been used by Mr. Grant in introducing the Central Provinces Tenancy Bill. India, however, is happier than Ireland in the absence of banded opposition on the part of her great landowners to all measures which would benefit the tenant by curtailing privileges which the landlord has usurped.

TEA IN AMERICA.

A GOOD deal has lately been said on this subject, and, especially during the past two or three years, the old project has again arisen by which the United States of America were to beindependent of China, Japan, or India. Of Indian teas America seldom took any, but confined her attention most exclusively to that of China. Recently, however, the reciprocal amenities which have resulted from the steam intercommunication of the Pacific States and Japan, and the trading facilities which such a traffic is sure to engender and encourage, have led America to turn her attention more to Japan than to China. We find within the last few years that the tea imports from China have materially decreased, while the discrepancy is more than made up by purchases from Japan. But now America wishes to grow and manufacture her own tea, and with that ambitious feeling which is characteristic of the American, she may be looking forward to a day in the not distant future, when she may help to supply the enormous demand which exists for that article in the United Kingdom and in Europe generally. Papers from America continually refer to this as being an important matter, and it is evidently engaging public attention across the Atlantic. Of course as in duty bound, we find the trade journals of Europe taking up the subject as well ; but we regret to observe that none of these journals deals up the subject in a practical manner. They all take it for granted that in the many varieties of climate obtainable in the States, some suitable locality will, as a matter of course, be found for tea, and that therefore the growth and spread of this industry is only a question of time, and, taking into consideration the energy and enterprise of the American character, it need not be a question of very long time. We have always affirmed on the contrary that tea-planting as a commercial speculation will never succeed in America, and, as this seems a suitable time for the purpose, we will proceed to state our reasons for having arrived at a conclusion so adverse to that reached by the great bulk of our contemporaries. There is a great difference between experimenting with a plant as a curiosity, and cultivating that same plant as a commercial undertaking, calculated to return a profit in hard cash to those who invest in the speculation ; and here it is that our contemporaries have erred. They have looked at and still look at it in the light of an interesting experiment, and seeing the success which has followed the few trials which have been made, they jump to the conclusion that these experiments only want expansion to lead to the accomplishment of a great end. We will quote a few instances to prove that this does not necessarily hold good. On the Sewalic Hills running from the Ganges north-west nearly to the Indus, and parallel to the great Himalaya range, the indigo plant grows wild, and in those beautiful plateau valleys, known as the Doons, and which are from 2,000 to 4,000 feet above sea level, the plant may be found freely growing in every direction, wherever a patch has been left uncultivated. It grows beautifully, and the locality is evidently its *habitat*. Arguing from this, several enterprising gentlemen built vats and planted out large tracts of land with the indigo plant,—with the result of dead failure. And it is a remarkable fact that we frequently succeed better with any given crop in a locality not so suitable—to all appearance,—to its wants than we do, if we persist in growing it where it would appear from surrounding circumstances and all the evidence available to us, Nature had originally planted it. Now with regard to this indigo, the plant grows beautifully, but it so happens that exactly at that particular time when the leaf is in its best condition for yielding the precious dye, the rains set in so heavily, that the value of the plant as a dye-yielding shrub is entirely lost. Nature possibly intended it for another purpose. The deer so plentiful in these parts eat it freely. But we want it for other purposes, and cut it to suit our own ends at a time when it would perhaps not be suitable if wanted otherwise. Now we shall come nearer home for another illustration. The plentiful supply of labour in the Hazareebagh district, led to the opening out of tea plantations in that locality, but these gardens cannot hope to succeed commercially. The tea made always sells at very low prices, and the quality is poor. True, labour is cheap and plentiful, and hence the cost of a pound of tea is very little ; still, we do not see much chance of success, as the drawbacks of a climatic nature are, we consider, too serious to be overcome bye such an accidental advantage as cheap labour. The rainfall is deficient, and in comparison of this all other advantages are as nothing. Another illustration, and we have done. We have recently been informed, by a gentleman of great agricultural experience, that the soil of the Western Dooars is not suitable for tea. He tells us that the soil is very rich, and two feet deep, and that the growth of the young plants is marvellous, shewing that the climate is all that could be desired. Hence the rush of speculators, to open out gardens in that locality. But we are next told that below those two feet of rich soil, there is nothing but gravel, and that of such a nature as will not permit the tap-root to penetrate. If this report be correct, tea as a commercial speculation in the Dooars will fail. So long as there is plenty of humus and plant-food in the upper stratum of soil, there is nothing to fear, but so soon as the tap-root reaches this gravel, and finds its way barred, the plants will cease to yield leaf in such quantity as will pay. The Hazreebagh difficulty is the one that the American cultivator will have to fear the most, although we are not quite sure how they propose getting over the labour difficulty, unless they can induce the negroes to join this class of work. It is not of the nature of work suitable at all for Europeans.

This difficulty, however, might be got over by enterprise and energy, but the climatic one appears to us fatal to the success of the scheme. Tea would grow very well in Calcutta, and yet we go to Assam and other places at a great distance. In Calcutta we have the necessary heat, and the soil, although not perhaps quite suitable, would suffice, but the rainfall is fatal to success. And it is exactly at this point that the enterprise in America will give way. The plant will grow beautifully, for the climate which grows rice and cotton successfully cannot fail to grow tea, but the rainfall of the Southern States is too meagre to make the plant flush sufficiently to pay. It is a common remark among planters that tea will not pay where the rainfall is under 100 inches and distributed over 8 months of the year. This may be taken as a truism, although there are some parts of India where tea grows and pays, and where the rainfall is considerably under 100 inches. At Dehra Doon for instance, where the rainfall averages 68 inches, tea does pay, the compensating influence there being the lesser degree of heat which prevails, and consequent diminution of evaporation, which makes 68 inches practically do the work of 100 inches. Whatever subsidiary advantages America may have, will not be sufficient to balance the deficiency in rainfall. We have examined the records of the United States' Agricultural Bureau for information on this point, and here is what we have found. The monthly rainfall of the State of Georgia averages in inches 4·11, 4·60, 6·60, 1·75, 1·09, 3·23, 1·82, 1·77, 3·62, 2·64, 2·74, 2·93; = total 36·9 inches. This is well distributed, but the quantity is very light. This lightness too appears in a strong light when we note that the slightest falls occur just when the tea plant wants rain most—in the hot and flushing months. If we assume the manufacturing season to extend over 7 months, say April to October, both inclusive, we have during that short but important season a total rainfall of only 16 inches, a quantity in our opinion which places the success of the proposed industry out of the question, so far as America is concerned. We know well that nothing will be wanting on the part of the American farmer to make the experiment turn out well, but he cannot, by any amount of energy, make up for a want of rainfall. Irrigation may be tried, but it is not so effectual as the natural fall of rain, and if there were no other cause operating to hinder the success of the enterprise, this alone would suffice.

EXPERIMENTS WITH PLOUGHS.

THE subject of improved ploughs for the use of the ryots is one that has received a good deal of attention of late, and experiments with various implements have been made. Some of these have been more successful than others, though as whole the results hitherto can hardly be said to have been very satisfactory. But when such experiments are being conducted, the public, who pay for them, have at least the right to demand that the operations be conducted by competent persons, so that fair and proper results may be obtained. This important condition, we regret to say, does not seem always to have met with the consideration it deserves. We have before us an official report of some experiments lately completed with "English ploughs" (the term is somewhat vague) in the Trichinopoly district, and they have resulted confessedly in failure. Reasons are of course assigned for this, and we proceed to reproduce them. In the first place we are told that the "Agricultural Inspector," a native, to whom the carrying out of the experiment was entrusted, was "altogether unfit for his work," a mere raw student in fact, with no practical knowledge of agriculture whatever. What, we ask, must be done to the man who appointed such a person to conduct important experiments? Mr. Benson, Acting Superintendent of the Government Farm at Saidapet, tells us, by way of apology, that "the man I sent I chose with reluctance, but he was the only one available who was at all likely to suit." If such were the case, all we can say is, better not to have undertaken the experiment at all. Mr. Benson, however, throws the blame back on the Government, and says "the late date at which the orders of Government were received prevented my choosing a really competent man to send with the ploughs :" and this brings us to the second reason assigned for the failure of the experiment, *viz.*, the lateness of the season. The ploughs were evidently despatched much too late, for work could not be actually commenced before the beginning of August (1879). The failure is also partly attributed to the deficiency of rain subsequent to sowing. If we look at the matter leniently, these last two excuses may perhaps be considered as valid; the former we will charitably assume was to some extent unavoidable, while the latter we will likewise suppose could not have been provided against, though it seems to us not improbable that the two are closely connected, and that, had the experiments been undertaken earlier, as they ought, the deficiency in the rain at the particular time it occurred would not have so materially affected the crop. But we purposely avoid picking holes in the above excuses, in order that we may bring the stronger light to bear on the impropriety of the major reason assigned, *viz.*, the incompetence of the instructor. The only merit in the excuse is its candour. As for the man himself, he seems to have had no idea of what he was required to do. We are told he "ploughed deeply where the result was to bring to the surface a subsoil of a harmful nature, and, so ingrained in his mind appeared to be the idea that his sole object as Instructor was to plough as deep into the ground as possible, that he constantly left off the work altogether on the ground that he had not strong enough bullocks." We are gravely informed that the strongest bullocks the Musiri tahsildar could procure did not content the Instructor, and so the Collector of Trichinopoly "sent out the strongest pair that the Trichinopoly tahsildar could procure." We should like to have given Mr. Martin credit for more sense. What could the worth of an experiment, carried on under such conditions, be? Needless to state this last instalment of bullocks met with no better fate than their predecessors, in the hands of the ferocious Instructor. Mr. Martin sorrowfully tells us that "after the lapse of 45 days these bullocks were returned in a shocking state from the treatment they had received, and I was obliged to pay Rs. 16-14 to the owner as compensation;"—an edifying sight this to the ryots, for whose special enlightenment these experiments are undertaken. We have said enough to give our readers an insight into the way in which we sometimes try to teach the ryots how to cultivate the soil; and then we wonder at their conservatism and stubborn rejection of our ideas. We fancy the ryots of Trichinopoly will not easily forget what they have witnessed. The whole experiment was thoroughly ridiculous. But what is more ridiculous than all, is Mr. Benson's grave official assurance that "the experience gained in this experiment is valuable, and not, considering the circumstances under which it was carried out, discouraging!" But, then, we must not remember that Mr. Benson is responsible for those "circumstances," that it is he who appointed the intelligent "Instructor." Mr. Benson does not stand alone, however. Almost equally good is Mr. Martin's report of the result of the entire experiment, *viz.*, that the ploughs have not made a "favourable impression" on the ryots. In the face of these specimens, what trust can be placed in official documents and reports? After the aforementioned encomium on the result of his nominee's labours, Mr. Benson urges the Board of Revenue that he experiment be repeated "under more favorable conditions." But the Board, while concurring in this opinion, do so from very different motives to that of the Collector and Superintendent. "For," sagely remarks the Board, "although the prospects of the ryots adopting European plough are very remote" [*very*, we should say] "yet it would be well to remove from their minds the unfavorable impression they may have formed on the subject"—if you can!

The principal objection to this plough is the usual one, *viz.*, its weight and unsuitability to the bullocks. But the Instructor knew nothing of the difference between deep *cultivation* and deep *ploughing*, and consequently, in the attempt to plough deeply, a bad subsoil was turned up, which resulted in a poor growth and the failure of the crop.

UMRITSUR CONSERVANCY.

WHEN we wrote recently on the subject of the important experiment which was being made at Poona, and which experiment we may repeat, has quite passed out of the tentative stage, we were not aware that Umritsur has for sometime been engaged on a similar experiment. Yet not quite similar. In Poona, the night-soil is removed to a convenient depôt outside the city, and with the help of the sweepings and other dry refuse, and the ashes says

is converted into *poudrette*, which is sold at one rupee per cubic yard—one cubic yard containing about 14 maunds. At Umritsur the whole of the conservancy filth is removed to a distance of some eight miles out of the town by the help of a sytem of sewers, which are flushed from the canals. At this depôt are two large natural depressions which with a little alteration are now used as tanks where the sewage is allowed to precipitate. This mechanical change having been effected, the comparatively clear liquid is run off and is purchased by the cultivators in the neighbourhood, the precipitated manure is then removed and stored in godowns for the purpose, whence it is purchased and removed by the surrounding ryots. An inspection report by the Sanitary Commissioner of the Punjab tells us that no smell results from this mode of treatment. Regarding the profit accruing to the Municipality, we are not in a position to speak positively, as we have no complete accounts before us. From the abstract we have seen, we should, however, imagine it to be a profitable undertaking. One peculiarity of these experiments is that they may be very profitable, and at the same time shew a heavy balance on the expenditure side of the account. The reason for this is that all such accounts include the cost of collecting the filth, that is to say the total charge for ordinary conservancy. This is not fair to the experiment, because without it, that expense would have to be borne at any rate, for sanitary reasons. We find from the accounts that the average income from sales of manure, solid and liquid, is over Rs. 25,000, and that the expenditure is about Rs. 50,000 annually; but it would be manifestly unfair to charge all of this latter sum to the experiment, because most probably the vastly greater part is due to purely conservancy services. This is a very interesting experiment inasmuch as all connected with it are on their mettle to show as large a balance at credit at the close of each year as they can; and by this means the streets and latrines of Umritsur are benefited.

What perhaps strikes an outsider most forcibly is the apparent ease with which a prejudice, hitherto considered invulnerable, can be grappled with and mastered when the opposite party have an advantage to offer. If there be one thing more than any other obnoxious to the native of India, it is the idea of having anything to do with night-soil and sewage generally. We know what use the thrifty Chinese cultivator has for all that matter, and how carefully he garners it up for his pet fields, but the idea of a native of India having anything to do with it is almost beyond belief. Yet here in two instances we find them not only using it, but paying for it, and, in the case of Poona, registering their orders accompanied with cash six months in advance, to ensure their getting it. The report on the Poona experiment says.—so anxious are the cultivators to get the new manure that guards have to watch the heaps of raw material in the city to prevent the ryots stealing it in that condition—and although we have no definite information on this point regarding the operations at Umritsur, we have the broad fact that the cultivators pay twenty-five thousand rupees a year for the material.' Thus will all prejudices fall, Dagon-like, before self-interest. Education has often been called the great lever which is to remove superstition and prejudice far away from the people. Commend us—while not despising the power of education—to self-interest. We shall be glad to hear of other large centres of population following the lead of these two important towns.

EDITORIAL NOTES.

As regards agricultural prospects, we extract the following from the last Government notice to hand, being the report for the week ending 19th October :—

Favourable rain has fallen in some Madras districts, and the north-east monsoon is reported to have broken in the Kistna district; more rain is still required in parts; but prospects, on the whole, remain fair. In Bombay there is little or no rain; and it is still wanted in Surat and parts of the Deccan. Good rain fell in most parts of Bengal, with much benefit to the standing crops, but more is still required in portions of Behar; *rabi* sowings are progressing satisfactorily. In the North-Western Provinces and Oudh rain is reported only from Benares and Fyzabad, and some is also believed to have fallen in Partabgarh; rain is urgently needed in most of the central districts. Failing a further fall, the *kharif* outturn will be poor, and much of the *rabi* area must be left unsown; some distress has begun to be felt among the poorer classes in Cawnpore, Lucknow, and Rae Bareilly; and in Allahabad, Jhansi, Sitapur, and Partabgarh prices are rising. In the Punjab there was slight rain in Sealkot, but none elsewhere; the yield of the autumn harvest will, it is expected, be below the average, In the Central Provinces there was general slight rain; but in Nagpur, Bhandara, and Bilaspur, where the fall was apparently better, the reaping of the *kharif* harvest has begun, and preparations for the spring crops are in progress. There was moderate rain in Burmah during the week; more is required in parts of Pegu and in Akyab; agricultural prospects are generally favourable. In Assam prospects remain good. In Mysore and Coorg the crops have been further benefited by the week's rainfall. In Berar and Hyderabad there were slight showers. No rain fell in the Centra India States, and it is badly wanted in places. In Rajputana also the weather was clear.

Prospects throughout the Empire continue, on the whole, fair, except in some districts of the North-Western Provinces and Oudh, where the insufficiency of rain has shortened the yield of the *kharif* crops and is likely to materially lessen the area usually put under spring crops.

The concluding paragraph is characteristic of these official reports. It does not at all represent the actual state of affairs in the N.-W. P. There can be no doubt that serious apprehensions of a severe drought are entertained, and we are glad to see the local Government are alive to the emergency and are taking active measures to minimise its evil results. The Government of the North-West Provinces has in fact just issued a circular authorising Collectors to issue Takavi advances to cultivators for the purpose of digging *kutcha* wells. The amount of these advances is left to the discretion of the district authorities, and they are to use their best endeavours to induce the people to apply freely for these loans and to dig as many wells as possible, to avert the severity of the apprehended drought. We are also glad to see that the usual formalities in the matter of stamped paper, &c., which so often prove a great deterrent to Government loans being applied for, are not to be observed in the case of these advances, and we trust that the district authorities will one and all act in the spirit of these orders. The advances, we are told, are not to bear interest for one year, at the end of which interest at 6¼ per cent. will be charged on all outstandings.

THERE is reason to fear that if more rain does not fall very shortly, the *rabi* crops over large areas in the Lucknow, Rae Bareilly, Allahabad, Benares, and Jhansi Divisions will remain unsown. Of course there is as yet no reason to fear that the stocks of the past two bumper harvests have run short or are likely soon to run short. So far as we have been able to ascertain, the markets are well supplied; but if the coming spring harvest should practically prove a failure, the strain on the food-supply cannot but tell eventually. That the local Government is alive to the threatened danger is manifest from the special concessions offered to cultivators and others to induce them to construct *kutcha* wells in tracts which are solely dependent on the rainfall for whatever crops they produce. These wells are dug expeditiously and at a trifling cost. During the scarcity of 1877-78, such wells proved the salvation of many a family. In the Agra district, plots of land which had been prepared for the *rabi* were sown with carrots, and the crop brought to perfection rapidly by frequent irrigation.

IT is not perhaps generally known that carrots form a very nourishing article of food. But what makes them specially valuable in a season of drought or scarcity is the comparatively short period required for them to come to maturity. Another valuable crop is maize, which has been successfully grown in the Lucknow Horticultural Garden during the winter months. Maize sown early in October came to perfection and was ready for food early in January. The above hints cannot be too widely made known, though we are afraid that it will be hard to overcome the obstinate conservatism of the otherwise submissive ryot. That maize should be grown at a season when his ancestors have for generations been accustomed to raise wheat and barley, is a thing which it will perhaps be hard to make the unsophisticated cultivator understand and carry into practice.

IN our last issue we reproduced a letter from "Hortus" to the *Times of India* inquiring the best means for preserving the roots

of flowers and other shrubs from the attacks of white ants. Below it we inserted a recipe sent by a correspondent to the *Indian Daily News* for which he claimed that "painted on the sides of beams, &c., it will effectually destroy white ants." We have now the pleasure to give the text of a reply to "Hortus" by J. C. L. who, writing in a recent issue of the Bombay paper, says :—

It appears the natives use a plant called *som or soma*, in the culture of sugarcane, to keep off white ants. Mr. Graham, in his catalogue of Bombay plants, states :—"Dr. Gibson mentions that it is often brought from a distance by farmers to extirpate white ants from their sugarcane fields. A bundle of twigs is put in the trough of the well, from which the field is watered, along with a bag of common salt, hard packed, so that it may dissolve gradually ; the water so impregnated destroys the ants without injuring the crop." This is confirmed by Dalzell and Dr. Birdwood. The latter says :—"Water passed through a bundle of *somaluta* (Sanscrit for *Som*) and a bag of salt, will extirpate white ants from a field watered with it," quoting the *Oriental Christian Spectator* as his authority. This plant is known to botanists as *Sarcostemma intermedium* D. C. Prod., VIII. 538 ; (*S. viminale*, Wight's contrib., p. 52); it is leafless and bears during the rainy season beautiful umbels of pure white flowers ; and is to be found throughout the Deccan, in Guzerat, the Isle of Perim, and in arid jungles all over India, twining extensively over milkbushes (*Euphorbia tirucalli*), and other trees.

REPLYING to questions relative to the best method of conducting the experiments in contemplation of the use of compressed food for cattle, Veterinary Surgeon J. H. Cox has, we are told, recommended to Government that in each of the districts named, *i.e.*, Bengal, Bombay, N.-W. Provinces, and the Punjab, the horses of one British cavalry regiment, two batteries of artilery, 200 commissariat bullocks, and 100 camels, shall be supplied with the food for six months. If it is found to answer as successfully as seems to be the case in private trials, the inventor claims for his plan the merit of saving in cost five lakhs per annum. The food is besides much more convenient and easily stored. We hear that 100 tons have been ordered to be dispatched at once to Candahar. As it had been discovered that small cakes stand the effects of climatic change better than large ones they are now manufactured of ½lb. weight only.

IN our October number we noted some remarks of the *Englishman*, giving instances of the increasing tendency on the part of the Government of India to enter into competition with private capital and private manufacturing and commercial enterprise. We now extract the following from the *Indian Daily News* on the same subject :—

In speaking the other day of forest operations, we said that many officials seemed to indulge in experiments quite outside the range of their legitimate work. A little reflection will show that this might with truth be said of the Government itself. We are not now speaking of those quasi-commercial experiments, which are continually being tried in our jails, in the manufacture of various articles , although when Government goes outside its own wants, and manufactures articles of general demand, advertising them for sale in various ways, we must say the same mistake is made. We now speak of *boná fide* commercial transactions, and at present will confine ourselves to two. These are coal and cinchona. Since the Government took over the East Indian Railway, the practice of selling Kurharballee coal has been continued. Before the transfer, it was urged that there could be no objection to the East Indian Railway Company selling as much coal as they could, but it seems to us that the objection, which applies to the Government doing so, applied with equal force to the Railway company doing it. The Company's dividends were guaranteed, hence it could compete with the trade on terms which were not fair to the latter. Now, however, we cannot conceive of any excuse which can be offered for the Government doing this work. The land was originally purchased by the company with the consent of the Government, that the company might raise their own coals, and thus effect a saving in working expenses. This done, the connection of the company with the coal trade should have ceased, and it is unfair that the Government should thus abuse the advantages it possesses to oppose honest trade, and we trust to hear of an immediate stop being put to the practice. When a railway is opened in a district, all within the reach of its influence expect to derive some benefit from it ; otherwise why should a monopoly of carriage be bestowed on it ?—for a railway charter is practically a monopoly. The Coal Companies doubtless looked forward to a share in these benefits and they received their share till the company commenced to work its own coal. To this no objection could be raised ; but when this guaranteed company not only stopped purchasing, but actually appeared in the market as a seller of coals, the matter seems to us to have called for a protest.

Now, let us look at the cinchona speculation. Year after year extensions go on in this industry, until a large portion of British Sikkim will soon be covered with the tree. In the early days of tea cultivation, when it was not quite certain whether tea would succeed, commercially, in this country, the Government took the initiative at once, and gave the experiment a fair trial. After a few years, when it appeared beyond the possibility of doubt that success would follow the industry, the Government at once sold all its properties, and relinquished to private enterprise all the experience they had gained ; and this is, indeed, one of the functions of Government. In connection with this cinchona experiment, we have all known for some years past that, properly attended to, it is bound to succeed ; and yet the State extensions go on and there does not seem any sign of the Government relinquishing the business. It cannot be for the convenience of manufacturing the febrifuge, for that, too, is a success, and, with the cultivation of the plant, should be handed over to private enterprise.

It is surely time our Chambers of Commerce and Trades Associations bestirred themselves in the matter.

A WRITER a short time ago in the Sind issue of the *Civil and Military Gazette* observed :—

"One cannot help being struck with the widespread alarm and ruin caused in a country, the agricultural operations of which (as those of Sind) depend upon an average annual height of inundation. The current season is a case in point, the height of the inundation of the river Indus being this day more than four feet below that of the corresponding date last year. The grain crops are just now in urgent need of water, but the smaller canals and *karias* are nearly dry, and a few days' delay in the supply of water must inevitably result in the utter failure of the crops over large areas of the country. In this state of affairs some zemindars whose lands adjoin the head-works of the Hyderabad Water Works have made an application to the Municipality to have their *karias* filled with water, by means of the pumping engine situated at Tanda Gidu, they agreeing to pay for the fuel and the use of the engine ; and there can be little doubt that a few hours' pumping from time to time will enable these zemindars to save the whole of their crops at a very trifling outlay."

This leads the writer to suggest that an irrigation company should be started on an extensive scale, with floating steam pumps, each with its tender for fuel, stationed at stated intervals at the banks of the Indus, ready at a moment's notice to irrigate their constituent's lands at any period of the year. There can be no doubt of its paying. Experience would soon determine the size of the district, which could be properly served by one pumping barge—

"I have no doubt that the zemindars would soon learn how to combine to construct and maintain amongst themselves the necessary channels for conveyance and distribution of the water ; and they would probably, if shown how to do it construct cheap earthen tanks above the surface of the land, through which the water for irrigation would be supplied, and such tanks would contain a reserve supply of water for use, *at discretion* ; they would soon learn to construct these channels of permanent and impermeable materials, and to distribute the cost amongst the participants in the advantages of the new method.

ACCORDING to a note in a recent botanical journal, the resinous substance found on the branches of *Larrea Mexicana* has been proposed as a substitute for lac in the preparation of lac dye. The plant (commonly known as the Creosote plant) which belongs to the natural order *Zygophylleae*, is a shrub from 4 to 6 feet high, growing in dense scrub-like masses in Mexico, especially on the borders of the Colorado desert, where its luxuriant growth forms an impenetrable mass of vegetation, effectually preventing the inroads of the drifting sand. The presence of this plant is said to be a sure indication of a sterile soil, little else being found where it flourishes, though the bright green of the foliage imparts a freshness to the surrounding scenery. The common name is derived from the fact that the plant has a strong creosote-like odour which is so powerful that no animal will touch it. The resinous matter to which the smell is due is abundant in all parts of the plant, the branches being frequently covered with it, in the same manner as true lac. The resin itself is of a light ruby colour. It is used by the natives in the treatment of rheumatism ; it is also used by the Indians for fixing their arrow heads to the shafts, and for forming into balls, which they kick before them as they journey from point to point of their trail.

MR. O'CONNOR's review of Indian Trade for 1879-80 shows that manufacturing industries in India, apart from those connected with cotton, jute, and silk are developing. During the year a company was formed to work a large paper mill at Lucknow, and another paper mill has actually been started at Gawlior by Maharajah Scindia. A factory for making sulphuric acid has been established at Rangoon; a woollen mill in the Punjab; and in other parts of India, various enterprises of a more or less promising nature are being carried on.

IN his review of the maritime trade of British India for 1879-80, Mr. O'Connor has the following paragraph on the trade with Arabia:—

Our principal export to Arabia is rice, of which 890,403 cwt. were exported last year, a quantity greatly in excess of the exports of previous years. Some wheat and other grain are also exported, and these, with coffee, twist, oil, silk goods, and spices, constitute the bulk of our exports to Arabia, the total value of which was about 70 lakhs of rupees. Sending coffee to Arabia seems like sending coals to Newcastle, but it is said that a good deal of it only goes there to pass out packed like Mocha coffee, and that it is sold as such, here and in Europe. It is also mixed with real Mocha.

And now native dealers have begun to buy and export Colney coffee for the same purpose!

THE Central Provinces administration report for the year 1879-80, by Mr. J. H. Morris, C.S.I., has just been published. The year was a good one for the Central Provinces; a year of fairly suitable seasons and plentiful harvests, and this after two years of general depression. The trade of the year shows a decrease under the head of exports of cotton, due to a failure of the crop. The grain trade also fell off; owing, it is said, to the more plentiful harvests in other provinces and the cessation of famine prices. The working of the Warora Coal Mines showed a loss during the year of nearly half a lakh. The machinery broke down, and the mines were flooded. It is believed, however, that when the improvements now in hand are finished, they will secure the profitable working of the mines for many years to come. For the year reported on, the yield was but 32,000 tons in the whole twelve months; but 1,000 tons a month is expected eventually.

THE foreign trade of the Punjab has naturally been considerably affected by the famine in Cashmere and the war in Afghanistan. From the report for the year 1879-80, now before us, it appears that the imports to British territory decreased by 12 per cent. in weight and 32 per cent. in value, while the exports to foreign countries though much the same in weight as last year, show an increase of 14 per cent. in value. The apparent diminished value of the trade during the last five years is attributed to the more moderate estimates of value adopted in pricing the articles imported and exported. The great difference of value between the imports and exports of Cashmere, noticed in the last report, has almost disappeared this year. The import of shawls, which was made in order to meet the expenses of the famine, has fallen off again to a mere nothing. The falling off of imports is explained by the loss of population, and the consequent failure of the indigenous manufactures. It is also due in part, no doubt, to the difficulty of procuring able-bodied coolies and ponies for carriage, as nearly all of these were employed in importing grain to the valley. The silk trade of Cashmere has suffered most of all, and it will take some years for it to recover its seemingly prosperous condition before 1878.

The gradual settling down of things in Yarkand and Kashgar, and possibly the visit of Mr. Elias to the former place, have affected the trade with Ladakh; and now that pilgrims have once more been allowed to proceed to India and Mecca, the trade may be expected to revive considerably. The falling off in the trade with Chinese Thibet is noticeable, though the reasons of this do not appear very clear. The decreased import of borax is, no doubt, due to the low price now obtainable for this article, which is being driven out of the European market by South American borax. As would be expected, there was a great falling-off in the trade with Bajaur and Barwah, tracts not subjected to the immediate influence of the march of British troops, but sufficiently near to be profoundly affected by the results of the war. The exports to Cabul and Sewestan show an increase of 20 and 50 per cent., due, in a large degree, to articles sent up for the consumption of the army. The Lieutenant-Governor remarks:—"It is doubtful if the money poured into Afghanistan has to any general extent induced the people of the country to purchase more largely, but the whole report on the trade with countries west of the province shows an abnormal state of things from which no satisfactory conclusion can be drawn."

THE resolution of the Lieutenant-Governor of Bengal on the Bhaugulpore Division has the following remarks on irrigation:—

Irrigation works do not exist and are not needed in the parts of the division north of the Ganges. In the southern parts there are numerous petty works constructed by the people themselves. Works on a large scale were opened a short time back by the Court of Wards on the Kharakpore estate, of the Maharajah of Darbhunga. Special interest attaches to this scheme as the undertaking of a private estate, and the Lieutenant-Governor desires that its working may be always noticed in the annual report. It is to be feared that the system of constructing large *bandhs* of dams on the lower courses of the hill streams in the Daman-i-koh has proved, as Mr. Oldham believes, a practical failure. The indigenous plan of forming small reservoirs in the upper sections of the upland ridges, before the waters gather force and volume, is found to be more successful and less costly.

WE extract the following from the Resolution of the Government of Bengal on the report of the Burdwan Division:—

Silk, jute, cotton, indigo, iron, brass, and bell metal are the principal industries of the division. In Midnapore, silk manufactures continues to decline, and the year under review six out of nine filatures in the Ghattal sub-division remained closed. In Beerbhoom the working was more profitable owing, as it seems, chiefly to the low rates of wages, no change having occurred in these for the past 25 years. Tusser silk manufacture is said to have revived in this district. Large quantities of this silk are also produced in Midnapore. The jute and cotton mills of Hooghly and Howrah were busy during the year, but the manufacture of country cloth is in a languishing state. Indigo factories exist in Midnapore, Bankoora, and Beerbhoom. In Midnapore the area under cultivation fell off in the past year, but there was a great improvement in the outturn as well as in the prices realized. In Bankoora and Beerbhoom the season was less favourable. No attempt has yet been made to start again the Bengal iron-works in Burdwan, so unfortunately closed, but there has been, it is said, some talk of re-opening the iron furnaces formerly worked at Mahomed Bazaar in Beerbhoom. The pottery works of Raneegunge are conducted on an extensive scale, and the ware is said to be hard and durable, of excellent quality and design. The output of the six leading coal companies at Raneegunge amounted to 163,639 tons during the year. They all mine on the English plan making large galleries, and leaving nearly one-third of the coal to support the roof. Accidents are rare at the mines.

THE address of H. E. Sir James Longden, K.C.M.G., Governor of Ceylon, on the opening of the session of the Legislative Council, on the 15th September, commences thus gloomily:—"I regret that, in opening another Session, I am unable to congratulate you on an unchecked continuance of the prosperity which notably distinguished the five years ending with 1878. All countries are subject to such vicissitudes, and connected—intimately connected—as Ceylon is with Europe, through its extensive and valuable trade, it could hardly escape sharing in the great commercial depression which has affected not England alone but the whole commercial world during the last three or four years, and which is only now slowly passing away. It is not only from outside that the prosperity of the Island has suffered. Unfavourable weather, leaf disease, and other causes have diminished the produce of coffee in many of the coffee districts, and the new and thriving industries of cinchona and tea are hardly yet sufficiently advanced to compensate for the decrease in the coffee crop. At such a time, it is satisfactory to me to be able to announce that the distress among the native peasantry in the Eastern, Northern, and North-Central Provinces, which occupied much of our anxious attention last year, has passed away, and that, on my visits during the recess to those provinces, I found that food was fairly abundant and cheap."

THE labours of the Government Cryptogamist are thus referred to in the address:—"The preliminary report made by the

scientific gentleman who was sent from England to carry on the investigations, set on foot by Mr. Morris, into the natural history of the coffee leaf desease, will be laid upon the table. It may fairly be hoped that the labours of Mr. Marshall Ward will result in a thorough knowledge of the manner in which the disease is propagated and communicated, and, as a consequence of this exact knowledge, a determination will be arrived at as to the best modes of extirpating the pest."

THE following on the Trade between India and Ceylon is taken from Mr. O'Connor's annual review for 1879-80 :—

Our trade with Ceylon has been described, in previous reviews, as mainly of an interportal kind, there being constant and extensive intercourse between the island and the southern ports of the Madras Presidency, whence thousands of Tamil labourers flock every year to the coffee plantations. The principal items of import, in a long list aggregating over 48½ lakhs in value, are coffee (3½ lakhs), cotton piece-goods of English manufacture (nearly 12½ lakhs), almost all coarse unbleached goods sent from Colombo to Tuticorin and other Madras ports, fresh and dried fruits and vegetables (about 8¼ lakhs), betel-nuts (over 10 lakhs), gunny bags (2 lakhs).

The list of exports is even longer than that of imports, and the aggregate value (200 lakhs) very much greater. The principal items are animals (mostly cattle) (8½ lakhs) Indian piece-goods (11 lakhs), coloured handkerchiefs figuring rather conspicuously, these being a favourite article of attire with natives of Madras, grain and pulse as shown below :—

	R.
Rice	1,38,89,565
Pulse	2,84,158
Gram	2,55,860
Wheat	80 476
Other sorts	56,524

Also—oils (over 3½ lakhs),oil-cake (3½ lakhs), provisions (over 4½ lakhs), mostly flour, dried fruits, vegetables, and salted fish, spices and essential seed (nearly 5 lakhs), these seeds being used mainly as spices for curries, some tobacco and teakwood. The staple of the trade, it will be seen, is rice. Of this 151,558 tons were exported in 1879-80, the average quantity exported annually for the four previous years having been 181,749 tons.

THE manufacture of paper from the fibre of sugarcane is one of the methods of utilizing waste products which might well be started in India. The owners of plantations in the United States are endeavouring to arrange for the manufacture of the pressed cane into paper at the sugar factories, in order to avoid the cost of transporting the bulky raw material to distant paper mills. The cane required for one hogshead of sugar will produce a ton of fibre ; and the only difficulty in the way of efficiently bleaching it, so as to give a perfectly white paper, is expected not to prove insurmountable.

SURGEON MAJOR G. BIDIE, Superintendent, Government Central Museum, reported to the Madras Government, on the 27th September, that specimens of the destructive larvæ found in the sugarcane, and also specimens of the canes infested with the insects, both from South Arcot, had been sent by him to the Secretary of the Entomological Society, London. The latter writes under date, London 27th August.—The larvæ in the bottle are similar but specificially distinct from those received from Queensland and British Guiana; but it is impossible to identify here by the larvæ alone as to the exact species. However, as to the cause and remedy, I have no doubt from my own experience at Penang, and from information from an extensive eastern planter lately at home, that the cultivators have the remedy in their own hands, and that it is simply the cleanliness of their plantations. It is in the refuse heaps of trash and other vegetable *débris* that these insects multiply, and if this was burnt and also the infested canes, the pests would show a very marked diminution indeed. Cocoanut palms in the Straits are infested with two beetles. My friend tells me that adjoining his estate are several smaller Chinese ones, where paddy husk, &c., is frequently allowed to accumulate, and then his own estate suffers by the arrival in due course of fresh swarms of these insect depredators. I am sure you will find that your native growers are a good deal to blame in this respect, and were I there, I have little doubt I could point out many choice breeding grounds which they have provided for their foes."

THE *Deccan Herald* in an article on "The Wheat Trade" writes as follows :—

We shall have this year throughout the wheat producing districts of India, a full *rabi* crop. A great deal more will be produced than will be required for Indian consumption. The large extent of acres under wheat is in consequence of the bad seasons in England. Indian cultivators have been induced to sow wheat in prospect of the demand which would be made for this season's crops. The demand in Great Britain, while it will be great, will not be remunerative for Indian wheat. The Indian carrying companies charge such high rates that it is impossible for Indian dealers to compete with the American in the British market. There is a general belief that the wheat crop of the United States for 1880 will be the heaviest ever harvested.

* * * * * * * * * * *

There is a sure market for a certain amount of Indian wheat in Britain. It is in demand there for purposes for which American wheat does not so well answer. That quantity, however, is not so great as to be a sufficient encouragement for extending the wheat cultivation of India, or to make the trade a very profitable one for the producers of this country. What will be done with the large crops which this season will produce? Wheat will have to become a more general article of food for the people of India. It would be the best thing for the country if more wheat were consumed in it.

THE American shippers, with the proverbial cuteness of their nation, have discovered that it is less expensive, and therefore more profitable, to export flour than wheat. The bran takes up space, increases the weight, and to a certain extent detracts from the value of the cargo, though useful on the farm for pigs and so forth ; and it is roughly calculated to pay the miller's bill for grinding. The lesson should not be altogether lost upon Indian wheat exporters. At a few central points, mills might be constructed with a view to prevent the waste of room and money entailed by the carriage of bran over so many thousand miles. The refuse would be acceptable to the owners of cattle, while the poor beasts would revel like common councilmen at a Lord Mayor's feast. If the Indian trade in wheat is to be maintained as a serious branch of commerce, small economies will have to be practised, and the expenditure kept as low as possible.

THE Shiraz correspondent of the *Times of India*, writing to that journal on the 4th October, says :—

Everything here remains quiet, and there is little to write about. About a year ago there was a rumour that the Persian Government contemplated the imposition of a duty of 30 per cent. on the export of opium, and, although nothing definite has transpired, I have reason to believe that the matter is still under consideration. Indeed, I believe we shall see such a duty imposed before very long. When this comes about, we may expect the culture of the poppy to be greatly extended. The yield is now about 6,500 chests annually.

The public health here is good and the weather pleasant, the nights being rather cold. We are in the midst of our wine-making season, and large quantities of grapes are daily arriving. Everyone here, whether he be a Mahomedan or a Jew, a European or an Armenian makes his own wine, and drinks it too.

The price of wheat has somewhat declined. The scarcity of rice no longer exists, good supplies of the new crop daily arriving.

WE take the following glowing account of the richness of the country in South-Western China from *La Province Chinoise du Yün-nan*, the new work by M. Emile Rocher of the Chinese, Imperial maritime customs. He is referring more particularly, to a visit made to Hsin-hsing-chou :—

"The productions of the district are very important. Rice, wheat, beans, fruit of all kinds, oil seed, opium, indigo, &c., &c., are all cultivated on a large scale. Sugarcane is also believed in by the farmers, but is only grown in small quantity, and, as it requires nearly two years to come to anything, they do not pay particular attention to it. The nature of the soil is here so fruitful that, after the farmers have reaped their rice, a second crop of wheat, beans, or mustard is sure to be ready for harvesting by the end of the year. The inhabitants of the district are gentle in manner, active in their habits, hospitable and, above everything else, dealers."

Mr. Rocher's description of these people and their charming country will certainly strengthen the hands of those who are urging the British Government to open up direct intercourse with this rich province.

THE *Times* lately pulished a compilation entitled "Our Progress in Ten Years," drawn up from a comparison of the returns of the Board of Trade for 1879-80 with those of ten years ago. There is but one branch of national wealth or industry that shows a decline and this is agriculture—the area under corn and green crops having fallen in ten years from 17,069,000 to 15,650,000 acres, a decline of 8 per cent. for the United Kingdom. This is, however, in some way compensated for by an increase in the number of cattle, *viz.*, 8 per cent in cows, 12 per cent in horses, 6 per cent. in pig,—the only set-off being a loss of 6 per cent. in sheep. "Finally," says the *Times*, "it is manifest that we have grown in prosperity much more than in population; and that every succeeding decade, in spite of an occasional crisis or reverse, sees Great Britain richer, wiser, and happier, thanks to the industry and *civic virtues* of her people."

MISCELLANEOUS ITEMS.

AMONG other works Messrs. W. H. Allen & Co. announce the following, which will interest many readers of the *Agriculturist*, *viz.*: "The Irrigation Works of India and their Financial Results," by Robert B. Buckley.

OUT of the numerous candidates, who have already appeared in the field for the agricultural scholarships offered to native students by the Government of Bengal, four names have been submitted to the local Government for selection by the committee, of which the Director of Public Instruction is a member.

A NEW class of cultivators is attracting the notice of the Lieutenant-Governor of Bengal. These are known locally as *Belati Grehusts*, and are Englishmen who have taken small grants from the zemindars of holdings in the Soopole jungles. They clear the forest and grow crops like native cultivators; each holding being about 200 beegahs. The Lieutenant-Governor has asked for further information.

A NEW industry has been introduced in connection with one of the Bombay cotton-mills. The National Spinning and Weaving Company of India have lately added a flour-mill branch to their business. The first cost of purchase of machinery &c., was about Rs. 1,700. The first quality of flour is supplied to some of the local mills for sizing cloth, and other qualities are sold at shops opened by the company in different parts of the city. The very first start has resulted in a profit; and the new industry promises to be very successful in the future.

THE Government of the N.-W. P. and Oudh have resolved upon making certain experiments with the steam-plough; and have instructed Mr. G E. List, Executive Engineer, to undertake them. Banda is the district, where the steam-plough will be used first. The land destroyed by the devouring *Kans* grass will be ploughed up and sown as an initial experiment.

AN American firm is said to have turned out a big plough. It is attached to a railway car, and can make one mile of excavation, 2 feet deep and 3 feet wide, every four hours, thus doing the work of about 1,000 men. The beam is of swamp oak, 8 inches by 14 inches. Its total weight is about 1,700lbs.

WHEN are we to look for the revival of cattle shows in South India? About twenty-three years ago public exhibitions of cattle and agricultural produce were regularly held in several districts of the Southern Presidency at an annual cost of from Rs. 13,000 to Rs. 35,000. The effects of the famine are surely over by this time.

AN Aurungabad correspondent states that, after the present crops of opium in Hyderabad territory have been collected, *no more* opium is to be grown in the Nizam's Dominions. The yield of opium has been large, and added to the revenue of the State.

THE Madras Government have sanctioned the payment to Mr. H. B. Grigg, of the honorarium of rupees one thousand for the compilation of the Manual of the Nilgiri District. The Board of Revenue in submitting their recommendation remarked that Mr. Grigg deserves their best thanks for the skill and judgment displayed in this compilation, on which evidently much careful labor has been bestowed. The chapters treating of Ethnology, Early History, the Revenue System, as well as the cultivation of the Tea, Coffee, and Chinchona industries specially deserve commendation. Government in endorsing the Board's encomium on the manner in which the work has been compiled, sanctioned the payment of the honorarium as well as a grant of twenty copies for Mr. Grigg's own use.

A RANGOON paper says that "steps are being taken by Mr. Routledge's agent in Bassein to obtain a site on the Thongzai river far a bamboo paper-making factory. The spot is said to be a good one to select, as bamboos can be floated down the Thongzai river nearly all the year round. They exist in millions, a few miles from the town, which is also on the line of railway, a convenience in the matter of transport."

INFORMATION has been received from Persia that the Persian Government owing to the fact that the harvest and crops are not generally sufficient to supply the internal requirements of the country, has considered it advisable to continue the prohibition imposed in January last, on the export of grain and provisions from all parts of the kingdom. This interdict extends alike to all the provinces, and applies to all grain, whether purchased and stored for the exporation previous to the issue of the notice or not.

THE Traffic Superintendent of the N. B. S. Railway, in his report for the month of August, draws attention to the large decrease (10,454 maunds) in the weight of jute carried during the month, as compared with the same month last year. Mr. Drury says: "When the immense quantity of jute produced this year throughout this part of the country, as compared with last, is borne in mind, the decrease assumes rather a serious aspect, as tending to show that the increased rate has had the effect of driving the traffic from the line. The falling off, in round figures, is 36 per cent., whereas double the weight lifted last year might reasonably (with the larger crop) have been looked for."

THE *Bangalore Spectator* writes:—Now is the time for the wet weather crop, and many a thiglur is busy sowing his plot of ground with potatoes. About Davenahully and Chota Ballapoor the potato is cultivated very extensively, and landholders find it a very paying article of produce. The price of this vegetable varies at present from 8 annas to 1 rupee per maund of eight viss. Seed potato is plentiful and good; it is curious, however, to remark that the natives prefer just now to sow the Poona kind, and several hundred maunds were lately imported for this purpose.

THE "potato bug" is not such a scare in America now, since a lucky farmer discovered by chance that the insect can be made to yield a valuable red dye. Who knows but the farmers will yet go raising potato bugs for the market.

THE monthly report of the United States Agricultural Department estimates the cotton crop as a 91 per cent. crop; this is 6 per cent. better than last year. The corn crop is also estimated at 91 per cent., being 4 per cent. below last year's estimate. These estimates are based on the appearance of the crop in the early part of September.

THE recent rains in Alabama U. S. have, it it said, done much damage to the cotton crops. The worm has commenced to eat the cotton, and likewise the rust is injuring it.

IN the cotton States of America, the cotton seed is all carefully made into oil, the quantity used being 410,000 tons annually, and the produce of each ton is 35 gallons of oil and 750lbs. of cake of admirable fattening qualities. Hence the total production will be over 14 millions of gallons of oil, and 137,000 tons of oilcake for cattle feeding.

SOME splendid specimens of fibre from the banana plant were exhibited at New Orleans recently. It is said that the yield of

one acre from this plant is 10,340lbs. of fibre, the value of which, added to the price of the fruit, makes it one of the most profitable agricultural speculations.

THE American papers have been full of descriptions of the largest farm on the Western continent, the famous Dalrymple Farm. This farm contains no less than 36,000 acres of arable lands, of which 24,000 acres are under wheat and 12,000 acres under oats. To harvest this crop 125 reaping machines were used, worked by 375 horses and mules. The wheat produce of this huge farm is calculated for this year at 432,000 bushels, about 990 American cart loads. That is to say, the farm would need 45 trains of 20 cars each to carry off its wheat crop.

A SUMMARY of Agricultural returns for Great Britain for 1880, shows that the number of acres under wheat in the present year is 2,909,148, or an increase of 18,904 over 1879. The number of acres under barley is 2,467,831, a falling off of 199,345 as compared with last year. The number of acres under oats is 2,796,905, an increase of 140,277. The number of acres under potatoes is 550,931 against 541,344 last year, or an increase of 9,587. The number of acres planted with hops was 66,737, or a decrease of 934. The return of live stock shows that the cattle in the United Kingdom in the present year is 5,912,046, against 5,856,356 last year, or an increase of 55,690. The number of sheep and lambs is 26,621,724, or a falling off of 1,535,356 compared with 1879. The number of pigs is 2,000,722, being 90,837 fewer than last year.

OFFICIAL PAPERS.

THE TASAR AND OTHER WILD SILKS OF INDIA.

GOVERNMENT OF MADRAS.

9th August 1880, No. 944.

FROM J. Shortt, Esq., M.D., Deputy Surgeon-General, Madras Army, (Retired), to R. Davidson, Esq., C.S.I., Chief Secretary to Government, Fort St. George, dated Yercaud, 6th January 1880.

WITH reference to G. O., dated 26th March 1879, No. 729, and the order thereon, wherein I have been requested to furnish such information as I can give on the subject of Tasar and other wild silks of India, I have the honor, in the first place, to reply to the question put by M. David of St. Etienne to Mr. Wardle in the Proceedings alluded to above.

Question, No. 1.—What is the chemical agent made use of by the natives to soften the cocoon and make it ready for reeling?

Answer—(a.)—The agent used by natives generally to dissolve the gum of the cocoons is wood-ashes, in a saturated solution of which the cocoons are boiled from twenty to thirty minutes, when they become softened and the thread loosened and fit to be reeled off.

(b.)—I have used a weak solution of diluted sulphuric acid to the water in which the cocoons were boiled with the same object successfully.

(c.)—A friend interested in the subject has reeled off some beautiful silk simply by throwing the cocoons into boiling water and leaving the pan on a charcoal fire to keep it hot, for some time stirring them about in the pan to allow of the gummy secretion being dissolved, after which the end of the thread is picked up either from the top of the cocoon or the end attached to the tree or twig, and some five or six are placed together and the fibres reeled off into a single strand, in the same manner as is done with silk from the *Bombyx mori*. The silk comes off quite clear, leaving a thin shell or parchment that formed the inner coating of the cocoon.

Question, No. 2.—Can the natives reel a cocoon more than a year old?

Answer.—They reel off silk from cocoons of any age without difficulty, not only from the perfect ones, but the old perforated ones from which the moth has escaped are used also, the silk being reeled off in short lengths about a foot or a little more, and [illegible] utilized in various ways.

Question, No. 3.—What is the length of time elapsing from the making of the cocoon and the time of the coming out of the moth; does not the time vary greatly?

Answer.—Yes. I have given it as nine months (*vide* Proceedings, Board of Revenue, dated 31st July 1871, No. 3188). Subsequent observation leads me to believe that the time varies greatly dependent on the climate, season, and state of health of the worm at the time it commences to spin the cocoon. Further observation is needed on this point. I have actually had cocoons in my possession for six months ere the moth perfected; the previous age of the cocoons before they came into my possession was not known.

Question, No. 4.—The cocoons in the bales are mixed in color, dark and light; are these different varieties, and are they found in the same spots?

Answer.—The cocoons are generally of two colors—dark and light. I believe this depends in a great measure on the food they consume, or rather on the particular tree on which they are found feeding; although growing in the same spot, occasionally I have found the two colors on the same tree. I do not believe the color is owing to varieties, but simply dependent on the food.

Owing to my retirement from the service and other circumstances connected therewith, I was unable to do anything in the continuation of my experiments with the Tasar silkworm cocoons in which I have always been interested. I did not altogether lose sight of the subject, and I have been trying to find out if they are to be found on these hills. All my efforts hitherto have been unsuccessful. I secured two female moths of the *Saturnia attas*, but could not find any cocoons either of this moth or that of the *Phalæna papia*, although I offered to give as much as one anna for each cocoon to the Mulialhes if they will search for them. When at Madras I was always able to secure any number of cocoons at three pies each. I have been anxious to procure cocoons with the view of establishing them up here, and to carry out some experiments that I have had in view for a long time; but the few friends I have written to at Madras were unable to procure me any more, especially as they are scattered about the suburbs of Madras, and frequently after a whole day's search a coolie may not secure more than one or two perhaps; here lies the difficulty, and it is this that makes the collection expensive.

If expense is no object, a large number of cocoons can always be collected about Madras and its suburbs.

I have now a species of moth from Malabar, the chrysalis of which is loosely enveloped, imperfectly often, with a covering of silk; specimens of this silk I have now the pleasure to submit for inspection, and am of opinion that these might be improved materially by domestication or crossing with other species. I have sent specimens of the moth to England for identification, and hoping to receive the same in time, I have hitherto delayed submitting this report to Government.

I should much like to carry out some experiments here with the *Phalæna paphia* and other species of moths, but I have not the means to do so, and experiments are always expensive.

I should have to go down to Madras myself to secure the cocoons for introduction up here, and to carry out the practice in vogue in Orissa, a full account of which I have given in the Proceedings of the Board of Revenue, dated 31st July 1871, No. 3188, already alluded to above, and to which I would beg to refer for particulars which I have given in detail.

When cocoons of the Tasar silk moth are collected, if intended for obtaining the silk, they should be killed at once by steaming, otherwise, as the age of these wild cocoons is not known, they will become damaged by the moths perforating the cocoons and escaping. The male and female cocoons can be readily recognised by their size, as those of the male are small, and those of the female large.

FROM Surgeon-Major G. Bidie, M.B., Superintendent, Government Central Museum, to C. G. Master, Esq., Secretary to Government, Revenue Department, dated Madras, 16th January 1880, No. 7.

In reply to G. O. No. 729, of 26th March 1879, requesting information regarding silkworms, I have the honor to report to his Grace the Governor in Council that there is but little practical information regarding these available in Madras, as the Tasar cocoons are not an article of traffic, nor the silk a product of the looms of Southern India. I arrange the available information under the heads specified by the Government of India.

2. *Enumeration of the different kinds of silkworms.*—There are, so far as is known here, but three species of silkworms found in the Madras Presidency, *viz.* :—

Antherea paphia (Linn.), the common Tasar silk insect.

Actias selene (Macleay).

Cricula sp. (Walker) apparently *C. trifenestra* (Helfer), but as the specimens are in bad order, it is difficult to be certain.

3. *District from which each kind is obtained, and in what quantities.*—*Antherea paphia* is common all over Southern India, but nowhere so abundant as to induce the natives to collect it or to render its collection remunerative. There are two distinct varieties of cocoons produced by this insect, *viz.*, one of moderate size and light color, and the other much larger, darker, thicker, and containing more gummy matter. At one time there was a doubt as to whether these two varieties might not be the produce of different species, but having recently examined the moths of the larger variety, I am able to say that these big cocoons also pertain to *Antherea paphia*; the only peculiarity as regards the insect being that the moth is of unusual size. There is also some ground to believe that the size and color of the cocoon is to a certain extent dependent on the nature of the food consumed by the worm; those fed on the *Zizyphus jujuba* apparently producing the biggest cocoons.

Actias selene.—This insect is sparsely diffused over Southern India wherever the tree on which it feeds (*Odina wodier*) is found. The cocoons, although of good color, are thin, difficult to reel, and of little value. They are nowhere abundant enough to be of any commercial importance.

Cricula sp.—This insect is limited in its range, being confined to Coorg and Wynaad, where it lives generally on *Careya arborea*, but sometimes on the mango which it strips completely of its foliage. It is gregarious in its habit, literally covering the trees on which it lives, and constructing its cocoons in large clusters firmly interwoven by connecting threads, and thatched externally with a number of the leaves, not detached from the tree, but simply bent down and fastened firmly to the external coating of

the cluster. The cocoons are of a bright golden yellow, reticulated and rather thin in their structure. If the silk could be reeled, it would be very pretty, and large quantities of the cocoons could be collected in Wynaad, should they prove of any commercial value.

4. *The species of worm from which each kind of silk is manufactured.*—So far as known to me silk is not made from wild worms in Southern India, except to a limited extent in the country of his Highness the Nizam of Hyderabad. The silk manufactured there is the produce of the ordinary Tasar insect.

5. *The trees on which the worms feed.*—The Tasar worm, *Antheraea paphia*, feeds by preference on *Zizyphus jujuba*, but is also found on *Terminalia catappa*, other species of *Terminalia*, *Casuarina muricata*, and *Wendlandia notoniana*. The *Actias selene* feeds exclusively, so far as I know, on *Odina wodier*. The haunt of the *Cricula* is *Careya arborea*, but it also lives on the mango trees.

6. *The uses to which the silk is put by the natives.*—The hill-men in Ganjam cut the cocoons into thin thongs, which they use for lashing the long barrels of their matchlocks to the stocks. It has lately been suggested that ligature thread for surgical purposes might be made from the Tasar cocoons, and some of it was tried in the General Hospital, Madras, and found useful, although less strong than that of ordinary silk.

7. *Markets where the cocoons can be purchased.*—The cocoons, as already stated, are not collected or sold in Southern India. To the remaining queries, Nos. 7, 8, and 9, I am not in a position to give any reply.

8. As regards the information required by M. David of St. Etienne, I regret to say that very little is known here, from the obvious reason that silk is not made from Tasar cocoons in Southern India. As remarked in paragraph 3, the dark and light-colored cocoons found about Madras are both the produce of *Antheraea paphia*. The difference in the size and color of the cocoons seem to depend to some extent on the nature and quantity of the food consumed by the larva.

9. I enclose a small cluster of the cocoons of the *Cricula*, the gregarious insect, divested of the leafy covering.

SELECTIONS.

MR. SIMMONDS ON FIBRES.

FROM a very interesting paper by P. L. Simmonds, author of "The Tropical Agriculturist," we have extracted the following on fibres, as being of interest to many of our readers :—

"Coir is one of the best materials for cables, on account of its lightness, elasticity, and strength. It is durable and little affected when wetted with salt water. Numerous instances have been related of ships furnished with this light, buoyant, and elastic material riding out a storm in security, while the stronger made though less elastic ropes of other vessels have snapped in two. Indeed until chain cables were so largely introduced, most of the ships navigating the Indian seas were furnished with coir cable. Of coir, and coir rope, about nine or ten million pounds are annually shipped from India. Much is prepared in Ceylon, but Cochin is noted as the port of shipment for the best quality of yarn, and many thousand cwt. are annually exported from there. In 1870, we imported from the East 168,544, cwts. of cable yarn of coir valued at 177,956*l*., 11,107, cwt. of coir cordage, valued at 13,547*l*., and 1,105, cwt. of coir fibre, value 21,347*l*. Probably the last named was intended for making matting and brush fibre, &c. Two hundred and eighty-four cwt. of ropes, twine, and strands were also imported in 1870, valued at 455*l*. The produce of fibre from the husk of one nut sometimes reaches 20 lbs. in weight.

AGAVE FIBRE.—Under the name of Mexi can grass, we imported into the United Kingdom about 19,000 cwt. of Agave fibre, cut short and cleanly prepared, which is used as a substitute for bristles in cheap nail and other brushes. It is locally called Slye, and is very extensively produced in the Isthmus of Tehuantepec, and the higher lands of Mexico. One man can prepare about 4 or 5lbs. of fibre per day.

Under the general names of pita, the *Brometia Karatas* is extensively grown in Mexico. With proper care in cutting the leaves in due season, the fibre would be found not merely equal; but much superior to hemp, while from the natural whiteness of its colour, it would admit of being manufactured into the finest goods without undergoing the destructive process of bleaching.

The fibre of *Agava Americans* is used for many purposes and is of great strength.

Under the name of Sisal hemp, a large trade is now carried on from Yucatan to the United States in the prepared fibre of the leaf of *Agava sisilana*, which is used in rope-making, and, when well made, it fetches nearly as high a price in the market as Manila hemp. Several thousands of tons are imported into the States annually. An acre of plants will yield more than a ton of fibre at the end of four or five years. This plant has been introduced into Jamaica and propagated in the Botanic gardens there, and 8,000 or 10,000 plants distributed over the island. The Americans are also growing it at Key West and the adjacent islands.

In Yucatan they get out this hemp by the simple and primitive manner of beating the leaf on a block with a club or mallet, and afterwards scraping it on a bench or a smooth log or pole, with one end on the ground and the other breast high. They employ a narrow piece of board with a triangular notch in the end, which is brought to an edge, and held nearly perpendicular when used. The leaf is laid on the pole, held with one hand, and scraped with the other. In order to get rid of the gum more readily, the beaten leaves are generally soaked either in water or in mud till they ferment, but from the nature of the gum, even a small amount of fermentation stains and weakens the fibres, although it materially facilitates the cleaning of them. Such is the difference in the value of these fibres got out by the two processes of fermenting the leaves before scraping, and that of beating and scraping the leaves at once before fermentation takes place, that in the London market Sisal hemp is worth but 12*l*. per ton, when the fibres have been soaked in water or mud ; yet the same fibres are worth 50*l*. per ton when got out before fermenting by the aid of pure water alone. It would seem that this difference in the price of the fibre will warrant a good deal of labour and expensive machinery to get out the article in the better state.

ALOE FIBRE.—In Russia aloe fibre fetches about 4*d*. or 5*d*. a pound. One manufacturer turns out about 20,000 lbs. monthly, almost all of which is exported to France, where it is used for making hats, paper, cordage, stair coverings, matting, &c. The process of fabrication is simple and inexpensive ; the machinery consists of an engine of 4-horse power, moving a pair of cylinders on a system of beaters or stampers. Close at hand are the reservoirs made of metal or masonry, which are used for washing or soaking. The leaf, cut green, is passed between the cylinders or under the stampers, by which means it is crushed without destroying the fibre ; it is then left to soak for six or eight hours, at the end of which time the separation of the various elements has taken place. Thirty leaves of aloe, two yards long each, yield on an average 2lbs. of fibre. It is packed at St. Denis in banks and pressed in sacks, about 1,2?9 lbs going to the ton measurement.

USEFUL FIBRES.—Most of our tropical colonies abound with valuable textile plants, some of which are considered troublesome weeds. Those of a ligneous nature will annually produce two crops of shoots, from which good fibre may be obtained, requiring no machinery whatever in preparing it for the market. The most easy and simple plan is to macerate the shoots until the cuticle or outer bark disadheres freely from the epidermis or true bark, when the latter will separate readily from the ligneous part, and requires but little labour or knowledge to wash, dry, and pack the fibre for market.

For the plantain, pinguin, and all similar herbaceous plants, machinery is absolutely necessary to separate and clean the fibre advantageously.

Many of the Hibiscus family yield strong and useful fibre. In India and in the Southern States of America, attempts have been made to utilize the fibre of the common ochro (*Hibiscus esculentus*). About three tons of this hemp can the raised on a single acre.

In India many of the malvaceous plants are extensively cultivated and highly esteemed for their fibre. The bark of *Hibiscus cannabinus* in Coromandel abounds in strong and tolerably soft fibres, which are employed as a substitute for hemp, and are made into a coarse sack cloth. In the North-West Provinces of India, it is very generally cultivated for cordage, and for domestic and agricultural purposes, but its fibre is more remarkable for fineness than for strength, and would be of use in our manufactories in making mixed fabrics.

Several species of the grass tribe (*Saccharum*) are employed for making ropes on the river Ganges or the Indus. For these purposes these fibres are well fitted, being light, tenacious, and capable of bearing without injury alternate exposure, to wet and dry.

Gomuti or *ejoo* fibre (*Arengx saccharifera*) is considered superior in the East to all others yet made use of for the manufacture of artificial tresses, imitation horse hair for stuffing and such like purposes.

The roots of *Butea frondosa* and *superba* are made into strong rope in India, *Saguerus lumphii* ? yields a fibrous web very fit for cables and long cordage. From the leaves of the oil palm (*Elais guineenses*) and wine palm, the natives make excellent line and rope in West Africa, indeed it is from this that they produce all their fishing lines and nets. In the Cape Colony various species of *Restio*, known under the common name of rope grass, are in frequent use for cordage. The fibre and rope made from the wild rhea (*Urtica*) or nettle species, are among the strongest known, but it is too dear to come into the markets as a rope-making material. In testing it in a rope manufactory its strength per square inch was found to be 844 ; 894 ; and when made with the fibre 900.

The average strength of rope made with the best hemp was determined after many experiments, carried on between the years 1803 and 1808, to be 805.

The Moorgha or Marool (*Sanseveira Zeylanica*) fibre is remarkable for its whiteness. A line four feet long, made of this fibre, according to Roxburgh, bore a weight of 120lbs. when a cord of the same size made of Russian hemp bore only 105lbs.

JUTE.—The well-known jute of commerce now occupies a most important position amongst the supplies of textile materials furnished to this country, our receipts being 200,000 tons. There are two species which afford the fibre, *viz*., *Corchorus capsularis* and *C. olitorius*. It is very largely cultivated throughout the Bengal Presidency, and is much used for bags, and for baling or packing cottons, which weigh each about 2lbs. ; and is also shipped in pieces about 30 yards, called gunnies, which weigh on an average 6lbs.

IMPROVEMENT IN NATIVE WELLS.

An improvement in the method employed, nearly universally, by the natives of this country, for raising water from wells for irrigation and other purposes, has been proposed lately, and is worth the attention of all those who are interested in improving the agricultural system of the country. It is intended to supersede the present plan of raising a *charsah* of water by means of two bullocks descending an inclined plane, and is carried out in the following manner. Alongside of the well a rough drum, constructed of wood, is erected so as to revolve on a stout, upright, wooden post. A light beam is attached to another and similar drum on the same post, below the first; and to the end of this beam is affixed the yoke for one or two bullocks or a buffalo. The two drums can be attached to one another, so that they both revolve together; or they can be detached from each other, in which case the upper drum can be turned independently. This is accomplished by means of an easily arranged trigger, worked by hand by the man who drives the bullocks. The *charsah* must be of the kind common in many parts of India, having a leathern spout, or neck, attached to a second rope besides the one which raises the *charsah*—so arranged as to discharge the water when the *charsah* has reached the proper height. Both ropes for raising and discharging are brought over their respective rollers, and passed round the drums, so that when the buffalo causes the latter to revolve, the *charsah* is raised and discharged, the buffalo being of course stopped at the proper point. As soon as the discharge is effected, the driver disconnects the upper drum from the lower when the *charsah* has sufficient weight to turn the upper drum backwards and unwind the rope until it reaches the surface of the water and becomes refilled of itself. The driver then again links the two drums together and repeats the operation. If it should be found that the two ropes are apt to get twisted together, this can be obviated by having one of them made up with a right hand, while the other has left hand twist. The advantages claimed for the new method are (1) a considerable saving of first cost in erecting the drum, &c, as compared with excavating the bullock run; (2) a very great economy of bullock power, because the animals are frequently resting and may feed while not actually *raising* water, whereas in the present method they have to re-ascend the inclined plane—which is often managed by the slow and toilsome process of walking backwards—in order to refill the *charsah*; (3) the labour of the driver is also greatly economised as he need never move at all or very seldom. Experience will be required to decide on the proper diameter of the drum, and of the bullock path, in order to give the best results according as only one bullock, or a pair of bullocks, or a buffalo, may be used. Doubtless also, some patience will be necessary in order to overcome the prejudices of natives of India against anything new, combined with the objections, too common among working classes throughout the world, to the introduction of mechanical means for diminishing labour, and throwing men and bullocks out of employ. The proposal is due, we believe, to Major G. Steel, B.S.C., of the Survey Department, and has been already practically tested by his brother Mr. H. W. Steel, C.S., Deputy Commissioner at Ferozepore, where the necessary apparatus was put up as a cost of about Rs. 40. As regards the economy of labour, it is estimated that one man and one buffalo can do the work of three men and three bullocks on the old method.—*Pioneer*.

HORSE AND MULE BREEDING IN INDIA.

The *Resumé* of Horse and Mule Breeding Operations in India, 1880, has recently been issued, and a copy has been sent to us by the General Superintendent. The subject is one of great importance to the Government, as bearing on the question of remounts, and of the supply of transport animals to the army. Recent operations in Afghanistan have shewn clearly the superiority of the pony and mule as baggage-carriers, as compared with the unwieldy and less hardy camel. We have ourselves done our best to bring this important subject prominently forward. We are pleased to observe, in perusing the memorandum under notice, that mule breeding occupies a prominent place in the operations of the department. The memorandum is largely filled with details of a technical kind, but we cannot help observing the thoroughness of all the arrangements, and the close attention bestowed on those prejudices of the natives most likely to interfere with the working out of the end in view. Liberal concessions are made in regard to rules at exhibitions, and every encouragement is offered to the private breeder to undertake this work as a profitable industry. Instead of the old system of stud breeding, with its costly details, the selected sires are to be distributed over 130 stations in the North-Western Provinces, Rajpootana, the Punjab, and Bombay, and only the owners of properly examined and passed mares will be permitted to share in the undoubted advantages of this new system. In connection with mules, it is pointed out that they are reared at very small cost, and that the value of the animal, as shown by the price Government has paid, is steadily rising. The average price given for mules at Rawul Pindee Fair, was as follows:—

1876-77	... ...	Rs. 131	12	6
1877-78	... ...	„ 129	0	0
1878-79	... ...	„ 159	0	0
1879-80	... ...	„ 191	14	0

At these prices, the breeder must necessarily make a large profit, as the rearing costs practically nothing, and does not in any way interfere with the ordinary occupations of a farmer.—*I. D. News*.

A RAILWAY TO GODRA: NEW RESOURCES.

Our readers are perhaps not aware that in the eastern talukas of the Panch Mahals, that is in Dohad and Malod, many products are cultivated in which a large and increasing business is transacted in Bombay. The land is among the richest in the presidency, producing regularly two crops a year under what is by no means a skilful system of cultivation. Wheat, oil seeds, and linseed are extensively grown. The wheat is not at present a grain of a food class, and it is often grown intermixed with gram, and from very carelessly assorted seed. But we believe that if a little attention were paid to the matter, there is no reason why wheat should not be produced quite equal in quality to any from the Central or North-Western Provinces. And mercantile men in Bombay are well aware how valuable such a grain would be as an article of export to Europe. Though the mass of the cultivators in this part of the Panch Mahals are rude and ignorant men, there are many large landholders of the highest castes who are quite alive to the importance of growing produce for foreign markets, and are able and willing to carry out any scheme which would hold out a fair promise of success towards that end. Most of the wheat which is grown in Dohad and Malod is now, we believe, exported towards Malwa, but the construction of the railway to Godra will, in all probability, cause much of it to change its direction towards Guzerat, and the cheapening of transit will cause it to become a remunerative article of export from Bombay if only the quality is improved. Much of the oil seed grown in those parts is already sent to Guzerat. Linseed is at present not extensively grown, but may be increased indefinitely. Why should not advances be made through the *Desais* and large landholders, if necessary, to the ryots for the production of a particular article, in the same way as advances are made almost every year to the cotton-growers of Broach? Dohad and Malod will be much nearer to the port of export, not merely in actual distance, but in respect of cost of carriage, than the districts of Northern India are, and can, of course, compete favourably with the latter, if only a little energy is shown in improving the article produced. What can be done in this way has been over and over again proved. We need refer only to Mr. Ashburner's energetic and successful advocacy of the improved type of cotton in Khandeish, which resulted in the complete and (in that district) universal displacement, in favour of it, of the old varieties. The ryots are ready enough to see where their own interests lie, and to adopt reasonable suggestions for furthering them. There are other important products, such especially as tobacco, which we need not enumerate here, for we have already said enough to show the commercial importance of extending the Anand branch of the B. B. and C. I. Railway to Godra, with as little delay as possible. The State trial now in progress will bring the town of Godra prominently before the public, and might we think, serve as a happy reason for attracting the attention of Government to the delay that has occurred in the construction of a line that has, we believe, been virtually sanctioned already.—*Times of India*.

AGRI-HORTICULTURAL GARDENS AT LAHORE.

The Punjab Agri-Horticultural Society's gardens at Lahore did much useful work during 1879-80, in the same direction as the Saharanpore and Lucknow gardens. The results reported in the experimental cultivation of the carob, the *prosopis*, the rain tree, *sorghum euchoena luxurians* (teosinte) generally corroborate those obtained in the N.-W. P. gardens, from the climate of which that of Lahore does, not differ so materially as does that of Calcutta. In arboriculture certain species of *eucalyptus*, notably the *saligna* or *resinifera*, have done well. The *E. rostrata*, which has proved so successful at Lucknow does not seem to have been tried at Lahore. The much vaunted *E. globulus* has proved, as elsewhere, a complete failure. The carobs have seeded; but the Superintendent appears surprised that all the seeds are not the same size. He recommends the seeds being sown singly in very small pots, after being soaked till swollen, and showing signs of germination. This plan might obviate the disappointment often experienced in the germination of this hard seed. The *prosopis*, or mesquit bean, has, as elsewhere, "a straggling appearance." In Cawnpore it is found to be more like a bramble than a tree; and Mr. Wright, in a recent circular, recommended its being grown in old brick kilns, the sides of which it would cover with a dense growth of a useful fodder plant. The *Pithecolobium saman*, or "rain-tree," has so far succeeded, contrary to the experience of Lucknow and Cawnpore, where frost has proved fatal to it. Experimental sowings of *sorgho* have proved it to be of no value as a cold weather crop; but as it has been grown successfully since 1876 when sown in May, the experiment of sowing it later seems of little value. As a grain crop it is not a success, and it does not therefore find favour with the ordinary cultivator, who likes more than one string to his bow, and in his *jowar* gets both grain and fodder. The saccharine properties of *sorgho* have not, however, been as yet fully utilized; it is pressed, in large quantities, in America, for sugar, with most successful results. The *moong phalli*, or pea-nut, was grown only with the result of proving that it will not succeed as a cold weather crop, and the remarks made on the experimental cultivation of *sorgho* are equally applicable here. The prickly comfrey is a distinct failure. The *Reana luxurians* has only been successful where grown with garden cultivation. The remarks of the Superintendent, Botanical Gardens, Singapore, are very much to the point:—"This grass, though useful, does not bear out its reputation in the Straits. Large quantities

of seed have been distributed, but all accounts state it pays far better to grow maize, as the same ground that will grow teosinte will produce excellent maize." This is also the experience of these provinces; at the same time the *Reana* is a far superior *fodder* plant to the ordinary *zea mays*, the stalks of which cattle will rarely eat, and which are constantly wasted or only used as fuel. The distributing work of the Lahore gardens was most successful. Large quantities of ornamental and useful plants and seeds (imported and acclimatised) were distributed throughout the province, and experiments in the introduction of new varieties of vegetables, trees, and flowers were successfully carried out. All that is wanted to put the Lahore gardens on a high footing, is the employment of a scientifically trained Superintendent. The available funds do not, however, at present allow of this extravagance, and Government appears disinclined to increase its annual grant. In spite of all difficulties, however, the Agri-Horticultural Society of Lahore deserves congratulation on the success obtained.—*Pioneer.*

RESIN AND TURPENTINE.

THE following account of the mode of production of resin and turpentine on the south-eastern coast of the United States is taken from an American paper :—" From Wilmington, N.C., southward, and nearly all the way to Florida, the pitch pine trees, with their blazed sides, attract the attention of the traveller. The lands for long stretches are almost worthless, and the only industry, beyond small patches for corn or cotton, is the 'boxing' of the pitch pine trees for the gum, as it is called, and the manufacture of turpentine and resin. There are several kinds of pine trees, including the white, spruce, yellow Roumany, and pitch pine. The latter is the only valuable one for boxing, and differs a little from the yellow pine, with which it is sometimes confounded in the north. The owners of these pine lands generally lease the 'privilege' for the business, and receive about 125 dols. for a 'crop,' which consists of 10,000 'boxes.' The boxes are cavities cut into the tree near the ground in such a way as to hold about a quart, and from one to four boxes are cut in each tree, the number depending upon its size. One man can attend to and gather the crop of 10,000 boxes during the season, which lasts from March to September. About three quarts of pitch or gum is the average production of each box, but to secure this amount, the bark of the tree above the box must be hacked away a little every fortnight. Doing this so often, and for successive seasons, removes the bark as high as can be easily reached, while the quality of the gum constantly decreases, in that it yields less spirit, as the turpentine is called, and then the trees are abandoned. The gum is scraped out of the boxes with a sort of wooden spoon, and at the close of the season, after the pitch on the exposed surface of the tree has become hard, it is removed by scraping, and is only good for resin as it produces no spirit. The gum sells for 1·50 dollars a barrel to the distillers. From 16 barrels of the crude gum, which is about the average capacity of the stills, 80 gallons of turpentine and 10 barrels of resin are made. The resin sells for from 1·40 dols. to 5 dols. per barrel, according to quality, and about pays for cost of gum and distilling, leaving the spirit, which sells for 40 cents. a gallon, as the profit of the business. Immense quantities of resin await shipment at the stations along the line, and the pleasant odour enters the car windows as we are whirled along. After the trees are unfit for further boxing, and are not suitable for lumber, they are sometimes used to manufacture tar, but the business is not very profitable, and is only done by large companies, who can thus use their surplus labour. The trees are cut up into wood, which is piled in a hole in the ground and covered with earth, and then burned the same as charcoal is burned elsewhere. The heat sweats out the gum, which, uniting with the smoke, runs off through a spout provided for the purpose. A cord of wood will make two barrels of tar, which sells for 1·50 dols. per barrel, and costs 37½ cents. to make. The charcoal is then sold for cooking purposes."

A NEW VEGETABLE FROM CHINA.

SOME experiments recently carried on by two or three Austrian and German horticulturists have brought into notice an almost forgotten plant, which was introduced into Europe from China nearly thirty years ago, but whose existence and whose products have been undeservedly lost sight of. This is the *Soja hispida*, a species of leguminous plant, somewhat resembling in habit and appearance the well-known pea. Unlike the latter, however, it has two distinct uses—industrial as well as alimentary. It is highly prized in China and Japan, and is said, indeed, to take its scientific title from the Japanese name of a sauce (sooja) which is made from its seeds. The seeds are very similar to a 'marrowfat' pea, but contain a large quantity of oil, which is either pressed out of them or boiled out in the process of cooking the seeds for the table, which is effected by simply throwing them into boiling water, when the outer skin bursts and floats to the surface, together with a quantity of oil, both the oil and the husks being skimmed off together. These may be either used as cattle food, or the oil may be separated and employed for various purposes, while the husks are still valuable as feeding stuff or as a manure. The peas are boiled for about twenty minutes, and furnish a dish which is highly relished, not only by the Celestials, but by many Europeans who have tasted it. It is said to resemble in flavour the green pea, but lacks its sweet taste. The boiled 'soja' is also prepared as a cake, and as a sauce, being fermented for the latter purpose, and salt, pepper, &c., being added. The sauce has a high reputation among the Chinese and Japanese, not only as a condiment, but as a medical agent. Chemical analysis of the seeds show them to be very rich in proteine. The oil is available for many uses—for burning in lamps or even as a substitute for olive oil. Being somewhat of a siccative nature, it is not adopted as a lubricant, but it is for that reason useful as a substitute of linseed oil in the manufacture of paints and in other similar industrial arts. Finally, to complete the list of virtues of this Celestial pea, the haulm forms an excellent fodder for cattle and horses. The plant seems well adapted for cultivation in many parts of Europe, and would probably do well in the warmer districts of England and Ireland. It remains to be seen whether the agricultural success of the German experimentalists will result in its general acceptance in Europe. We must, perhaps, accept the foregoing statement from the *British Mail* with some reservation, and shall look with much interest for the advent of this interesting stranger.

THE CEREAL HARVEST OF THE WORLD IN 1880.

THE annual volume on the crops of the various corn-growing countries of the world has just been issued by Mons. Bruy Estienne, of Marseilles, and the reports it contains occupy several hundred large quarto pages. A map showing in various colours the state of the wheat crop in the different departments of France is also given. Of the whole of the cereal crops of France the reports are good. The wheat crop is in five departments very good, in 17 departments good, in 26 departments fairly good (*assez bonne*), in 16 departments medium, and in six departments, only bad. Oats are very good in 28 departments, good in 40 departments, fairly good in seven departments, medium in six departments, bad in two departments, and very bad in one department. The maize crop, grown chiefly in the southern departments, is fairly good. In three departments it is very good, in 19 good, in five fairly good, in five medium, and in one only bad. Rye is reported as very good in 11 departments, good in 53 departments, fairly good in six departments, and medium in three departments. Barley is the best crop of the year in France. In 26 departments it is very good, in 40 good, in five fairly good, and in three medium. In no department is either the rye or barley crop declared to be bad. So far as other countries are concerned, with the exception only of Russia, the reports are generally favourable. In Upper Italy the crops are reported as yielding 30 per cent. above the average. Roumelia and Upper and Lower Bavaria stand next on the list with a produce of 25 per cent. over average, and these are followed by Podolia and Swabia with an over average production of 20 per cent. In the south of Italy and Bavaria, and in Wurtemburg the estimates of crops are 15 per cent. over average; while in Bessarabia they are 10 per cent. over. The crops of the year are 5 per cent. over average in Hungary, Poland, Belgium, and the United States of America. Average crops, without either surplus or deficit, have been grown in Prussia, the Palatinate, Baden, Switzerland, Denmark, Sweden, Norway, Central Italy, Holland, the North of Russia, Servia, and Egypt. Deficiencies of 5 per cent. are reported in Great Britain, Ireland, and Saxony. In Courland the deficiency is put down at 20 per cent., and in Gothland another Russian province, at 25 per cent. under average. In Central Russia the crops are so bad that the deficit is estimated at 40 per cent. below average. The commercial summary which accompanies the report shows that Europe will largely depend for much of her breadstuffs from America, and that there is every prospect of fairly good and remunerative prices being obtained for cereals this year.

AGRI-HORTICULTURAL SOCIETY OF INDIA.

The usual Monthly General Meeting was held on Thursday, the 23rd September 1880.

W. H. COGSWELL, ESQ., V. P., *in the Chair.*

THE proceedings of the last Meeting were read and confirmed.

The following were elected Members :—

Rai Jaikissen, Captain W. A. J. Wallace, Messrs. Charles Ryves and A. B. Holmes.

The names of the following were submitted for Membership :—

The Maharajah of Churkaree Bundelcund,—proposed by the Secretary, seconded by Baboo P. C. Mitter.

The Manager of the Tarrapore Tea Company Burtall Division—proposed by the Secretary, seconded by Mr. J. E. MacLachlan.

James Strachan, Esq., C.E., Engineer and Secretary to the Kurrachee Municipality,—proposed by Mr. J. J. Cumming, seconded by the Secretary.

Rejoined.—D. W. Taylor, Esq., Grantee, Ouidh, R. M. Daly, Esq., H. M. Bengal Marine, and Poornanund Burroah, Esq., Extra Assistant Commissioner, Deebroghur.

CONTRIBUTION.

A small collection of plants (Orchids, &c.) from Borneo. Presented by Colonel W. M. Lees, on behalf of his brother, the Governor of Labuan. These have arrived in good condition.

Five kinds of Indian corn raised from American seed. Presented by Charles Girdlestone, Esq., Resident in Nepal.

The following is a memorandum from Mr. Girdlestone respecting these specimens :—

The five different kinds of Indian corn, of which single specimens are herewith sent, were grown in the private grounds of the Nepal Residency from seed directly imported from America in the spring of this year. The seeds were sent by a Virginian planter. The smallest cob, with grains like seed pearls, is the pop corn. The other four kinds were only distinguished by the sender according to colour.

The corn has been grown in good loam, which had previously been ploughed three times by the Government plough made at the Cawnpore Farm, and fairly but not richly manured with stable and cow-house refuse. In a season which has been favourable for this crop, it took about a fortnight longer to mature than the ordinary Indian corn of this valley. The yield has been about one-fourth more than the ordinary kind grown in ground of a similar character and similarly prepared. Some of the stalks attained a height of 14 feet. The leaf is broader and the stem thicker than the indigenous kind, but I do not think that the plant covered more ground. The height of the Residency grounds is about 4,700 feet above the sea, and the average maximum temperature in the shade about 85 F.; the sun maximum *in vacuo* about 150 F., during the month that the crop has been growing.

The Secretary placed on the table specimens of four kinds of Indian corn from the supply received this season from the Society's seedsmen in Philadelphia. The Nepal raised corn contrasts favourably with them. The Secretary added that, to the best of his recollection, such fine specimens of Indian growth from imported seed had not been previously submitted to the Society.

Agreed, that these specimens be carefully preserved for trial in due season in the Society's Garden in order to ascertain, if any, and what deterioration occurs.

A small collection of plants and seed from the Nicobars. From E. H. Man, Esq.

Some plants (25) of the Ceara Rubber tree. From the Officiating Superintendent, Royal Botanic Garden, Calcutta.

A quantity of acclimatized Aster seed. From C. Nickels, Esq., (Available to Members).

Mr. George Bartlett sent for the inspection of Members a fine grown plant of *Croton Kingii*. Mr. Bartlett, affords the following information regarding this plant:—

"During a casual visit to Barrackpore three years ago, I observed a sickly plant of *C. pictum* growing under the shade of some trees, in fact, the plants appeared to be on its last legs from starvation and want of light. On examining the plant, I found one branch with the variegation of C. Kingii, although a very sickly one I secured it, and with much care and nursing it has developed to its present state. The suffusion of a delicate salmon pink over the surface of the leaf, whilst the costa being of a bright pink, gives the plant a pleasing and decided character. With the approval and permission of Dr. King I have named it after him."

PLOUGHS.

Submitted the following letter from Mr. W. Crawley of Cawnpore, regarding the report from the Committee on the plough forwarded by him for competitive trial :—

I have to acknowledge receipt of the report of your Sub-Committee on the Cawnpore plough. I must respectfully demur from the decision arrived at.

Your Committee report that the plough cut a sod 5 in. wide and 4 or 5in. deep ; now this is the average work which an English plough does with a pair of strong horses. *It is unnecessary for me to tell you that* the plough was never made to do such work as this with a pair of light Bengalee bullocks.

The plough failed to turn the sod over, this is its speciality, it was made so as not to turn the sod over, but simply to raise and pulverize it (by means of its forked mouldboard) and drop it again, *without bringing any new soil to the surface.* I quote a paragraph from the *Pioneer* of 31st August, in support of the principle on which the plough is made. Mr. Mechi of Tiptree, one of the most practical agriculturists of the present day says, that though the wheat plant sends its roots several feet into the ground where the subsoil is sufficiently loose, it "uses these roots more as a means of supplying itself with the moisture necessary for its existence. It is in the surface soil that the fibres seek for and obtain the principle elements of their food, in the presence of greatly increased heat and action. In the poor subsoil there is comparatively nothing for them, but water, for Liebig has proved that the few inches of surface soil have the power to fix or retain all the ammonia, potash, and phosphate of lime applied to it, and these are the three main requisites of plant food." Mr. Mechi advocates deep ploughing or cultivation, while keeping the subsoil in its place. The subsoil should be thoroughly stirred with the "grubber" or "cultivator," which will disturb it without bringing it to the surface or mixing it with the fertile and friable top soil.

The plough being somewhat novel in shape, and in the absence of instructions as to its working, and the object for which it was made, your Committee considered, I presume, that to be thoroughly effective it should have turned the sod completely over.

BAMIEH COTTON.

Submitted a letter from the Under-Secretary, Government of India, Home, Revenue, and Agricultural Department, forwarding a collection of papers and a note regarding the cultivation of Bamieh Cotton in India, and asking for a report on the result of experiments made with the additional quantity of seed received by the Society direct from Egypt in June 1878.

The Secretary placed on the table replies from several persons, to whom portions of the seed in question had been sent, including one from Mr. Westfield, with a photograph of one of his plants laden with bolls.

Agreed, that copies of these be forwarded to Government in reply to their inquiry.

COTTON-SEED OIL.

Read the following letter from Baboo Peary Chand Mittra, V. P., on the above subject :—

"In looking recently over some old publications of the Society, I observed a short paper, written so long ago as 1837, by Mr. Charles Lyall, of the then firm of Lyall Matheson & Co., 'on the value of cotton seed for oil.' Mr. Lyall gives extract of a letter, dated October 1836, from a correspondent in New York, on this subject, which is, I think worthy of reproduction, and have accordingly annexed it, as probably few, if any, of the present Members of the Society have a copy of the 'Transactions' (Vol. 4,) from which this extract is copied, to refer to.

"I am not aware if much, if any, cotton seed-oil is now exported from Egypt, nor what the export, if any from Bengal, may be ; but it does seem strange that when there is such an abundance of the material at hand, and when the demand for all kinds of oil is on the increase, that this particular kind should not be added to the many exports from Calcutta. Perhaps the insertion of this note in our monthly Proceedings may have the effect of drawing attention to, and eliciting some information on this subject.

"Presuming it may interest the agricultural interests of Bengal, I deem it proper to mention that within a few days past, we have received orders at this Agency, from his Highness the Pasha of Egypt, for all the necessary machinery, &c., for Steam Rice Mill, for husking and cleaning rice on an extensive scale, by the improved process employed in this city and in South Carolina and Georgia : also for a Cotton Seed Oil Mill to be worked by steam power according to the patent process extensively used in this country, where the oil is now manufactured in large quantities and sells for about one dollar per gallon. It burns equal to the best spermaceti and is successfully used as a substitute for almost every other kind of oil.

"One bushel of seeds yields about 2 quarts of oil, the outer rind or pellicle of the seed supplies the only fuel used in working the steam engine ; all the machinery and apparatus for an establishment capable of manufacturing about 300 gallons of oil per day, will cost about 15,000 dollars delivered on board in this port."

In connection with the above the Secretary drew the attention of the Meeting to specimens of Upland Georgia cotton-seed oil presented to the Society in 1838, by Dr Huffnagle an Honorary Member and Consul to the United States ; also from Mr. C. B. Taylor of Palamow in 1845, and from Major T. Davis of Buldana in 1855. Though the subject had been frequently brought to notice by the Society at various times yet, to the present day, not a single gallon of this useful oil had been exported from this side of India, whilst from the United States of America, the export had considerably increased, as the following extract from a recent number of the *Times* would shew :—

"COTTON OIL.—The manufacture of cotton oil from the cotton seed is becoming of importance in the United States, there being at the present time upwards of 41 oil mills, of which nine are in Mississippi, nine in Louisiana, eight in Tennessee, six in Texas, four in Arkansas, two in Missouri, two in Alabama, and one in Georgia. The annual quantity of seed converted into oil now amounts to about 4,10,000 tons, the yield being at the rate of some 35 gallons of oil to the ton of cotton material. Moreover, each ton leaves 750lbs. of oil cake of admirable fattening qualities. A great deal of the cotton oil is imported to Italy and other countries where the olive oil is a staple ; and, in point of fact, cotton oil is there superseding the olive oil, not only for utilitarian purposes, but also as an article of food. It is said, too, that the use of cotton oil in this way is gaining ground in some parts of the States. The following are the statistics of consumption :—

	Export. Gallons.	Home Consumption. Gallons.
1876-7	... 1,816,000	... 2,000,000
1877-8	... 1,457,000	... 1,800,000
1878-9	... 5,750,000	... 2,425,000

—*Times* of 13th August 1880."]

It would appear that cotton seed is also becoming one of the principal articles of export from Egypt. It has gradually risen from 1,000 cwts. in 1860, to about 3,500,000 cwts. in 1873 of the value of £777,000, and England takes nearly all this. During the last 20 years the imports of this seed into England have risen from twenty thousand tons to two hundred and thirty thousand tons. Cattle, as is well known, take readily to it and thrive upon it. In the United States it is used largely as a manure for Indian corn and indeed as a general fertiliser.

The Chairman remarked that the cattle connected with the Gossery Mills throve well upon cotton seed. Dr. Lynch observed he had been informed that it was largely employed for this purpose in the Upper Provinces.

RHEA FIBRE.

The Secretary next called attention to a letter from the Under-Secretary to the Government of India, to the Secretary to the Chamber of Commerce, forwarding samples of Rhea fibre in the bleached and half bleached state, prepared in Lancashire, and requesting a report upon the quality and value of the fibre. These specimens Mr. Wood had handed to him (the Secretary) for his opinion, and he had submitted the following memorandum in reply :—

These samples are very beautiful and of excellent quality, but the commercial value cannot be given here as it is almost an unknown article in this state of fineness. We have no machinery here to work it into cloth. The home market is the best test. There it would probably be valued as high as £2,000 per ton. Such was the value affixed on a sample similar to this in the possession of the Agricultural and Horticultural Society, which was also prepared in England from plants grown in a large glass-house.

As far as my experience extends, the parties in England interested in Rhea fibre prefer to obtain it from India in the raw state, as the cost of the after processes for preparation in the state of the samples now before me, is comparatively small, and when so prepared the fibre sells for a large figure.

I have also seen specimens somewhat similar to these prepared some years ago at Saharunpore from plants raised there ; but it was I believe, a tedious and expensive process as the experimenters were new to the work and had not the necessary appliances readily at hand.

Letters were read—

From the Director, Department of Agriculture, N.-W. P., forwarding a specimen of gum, and requesting an opinion on its commercial value.

The Secretary stated that this Acacia Gum is in a very dirty state and not worth more than from Rs. 8 to 9 a maund in the local market. To contrast with it he had sent the Director a picked specimen of gum from *Acacia Arabica*, which is quoted as high as three shillings per pound in the English market.

From Colonel H. R. Wintle, applying for a small quantity of good kind of potato, and offering a quantity of acclimated flower seed for distribution among the Members of the Society.

The Secretary intimated that he had complied with Colonel Wintle's request, and had accepted his offer of flower seeds.

From Colonel Lucie Smith, Commissioner of Chattarghur, C.P., inquiring about Reana luxurians and if the seed be procurable. (A large quantity of seed forwarded.)

From Secretary Smithsonian Institution, Washington, returning thanks for certain publications of the Society.

From Director, Department of Agriculture, N.-W. P., to the same effect.

MINERALOGY.

SOME practised gold diggers from Australia have already arrived at Madras, and are to be sent up at once to work in the Kolar gold field. A Superintendent for the same mines is also expected from Australia.

A RECENT number of the *Statist* gives a list of fifteen companies started for the purpose of working our Indian gold mines. The aggregate capital of the whole fifteen is £2,680,500, which gives an average capital of £178,700 for each Company. The Indian Gold Fieds Co-operative Association (registered April 27, 1880) has a capital of £1,200,000, while the Indian estates syndicate has a capital of but £3,000.

WE are informed that arrangements have been concluded by which the connection of Messrs. Tremayne and Co. with the "Wynaad Gold Mining Company" comes to an end, and the Secretaryship of the concern is transferred to Messrs. C. H. B. Forbes and Co., who undertake its management with the co-operation of an influential directorate. It appears that there is a concurrence of competent professional opinion, quite independent of the late agents, to prove that the reefs on the property are highly auriferous, and that, properly developed, they should prove extremely valuable.

WE have received a copy of the proceedings of the Wynaad Planting and Mining Association, held last month, from which we observe that our planting friends are about to apply for the services of a thoroughly qualified Mining Engineer to report on the whole of South Wynaad. In the Annual Report of the Committee we find the following affecting the gold industry :—

Your Committee cannot conclude their report without an allusion to the rapidly increasing development of the gold industry in South Wynaad. Since our half-yearly meeting, prospecting has been energetically pursued, and results have been better than the most sanguine dared to hope for ; gold has been found on several properties from Vythery to Teriott, on the one side, and from Vythery to Mopernaad and Cherambady on the other ; mining experts have reported favourably on the auriferous nature of the reefs, and gold has also been washed from the alluvial in various parts of our district.

We regret we have not space to publish the proceedings *in extenso*.

MR. A. INOSTRANJEFF describes in the *Neues Jahrsuch fur Mineralogie*, a peculiar variety of coal which occurs on the north-western banks of Lake Onega, Russia, in slates states to belong to the Huronian formation. It differs in its physical, as well as its chemical, properties, both from anthracite and graphite. Pure varieties show a strong metallic lustre, which remains, even after exposure to a dull red heat. Its hardness varies from 3·5 to 4, and its density at 4 deg. C. is 1·841. It is highly hygroscopic, an analysis yielding :—Carbon, 95·50 ; hydrogen, 0·40 ; nitrogen, 0·41 ; water, 7·76 ; and ash 1·01 When free from water the percentage of carbon runs up to 98·11 per cent., so that it is richer in carbon than anthracite, though it contains less hydrogen, no oxygen, and much nitrogen. The "black earth" from Olones is distinguished from graphite, which it resembles much, by the fact that it does not yield graphitic acid or "Brody's graphite" when treated with a mixture of nitric and sulphuric acids, nor does it burn as rapidly as graphite.

THE official journal of the vilayet of Yemen, *Sanâ*, announces that a gold mine has been discovered in the Sanâ district, in Arabia, and in the usual style of Oriental expansiveness, declares that this mine is "one of the richest in the world." A detachment of soldiers has been sent to guard the place against the attacks of Bedouins, and a commission has been appointed to examine and report upon the mineral prospects. A productive gold mine would be a useful acquisition just now to the Turkish Government.

IT is said that the South African diamond fields produced no less than three millions five hundred thousand pounds worth of gems in the last twelve months.

ACCORDING to the Australian papers, there has been a great rush to the newly-discovered gold field at Temora, near Sydney. The chief obstacle to the full development of the field is the want of water for puddling purposes ; unless plenty of water can be stored, the miners will soon be unable to carry on business. At present they are living on their capital.

THE mineral resources of Tasmania continue to be developed in a manner and with results which are very satisfactory. The Governor in his speech at the opening of the Tasmania Parliament said :—"The quantity of gold raised is larger than at any former period, and is steadily increasing. The production of tin may now be regarded as one of the permanent industries of the country ; and as an article of export it ranks second only to wool in the declared values shown by the statistical returns." But satisfactory as has been the progress made by the colony during the past few years, the want of more extensive communications, especial ly railways, is much felt.

WE gather from an interesting letter descriptive of Modern Brazil in the *Times*, that those wonders of the gold and diamond fields of Minas Gemes, which yielded so many millions during the last century, and part of the present, which "enable an extravagant Governor at Ouro Preto to shoe his horses with gold in solemn religious processions," which "enriched the reigning dynasty with £3,000,000 worth of diamonds, and set on the Portuguese and Brazilian diadems those two famous jewels, the Southern Star and the Abacete, rivalling the glories of the Koh-i-Noor," are in a great measure things of the past. Hardly 1,000 men are now at work in those diggings which formerly employed 80,000, and the outcome of their labours does not go for much among the items of the Budget. A few foreign companies, chiefly English, however, have taken up the abandoned shafts, and are now working the mines of Morro, Velho, Pary, and other localities, from which they extract gold to the yearly amount of £280,000 to £300,000.

GOLD MINES IN JAPAN.

FROM a consular report just issued, it appears that three gold mine. are now being worked at Shimor Aikawa, in the island of Sados They were first discovered in 1613, since which time they have been steadily worked by manual labour until 1869, in which year machinery was introduced by the Government. The main shaft is sunk to a depth of about 600ft., and two of the mines are connected by a gallery 3,000ft. in length. First-class ore contains from 50 to 2,000 yen worth of gold per ton (one yen equals 4s. 2d.). The ore is crushed at the top of the mine, reduced to powder by stamps, and ground up with mercury into an amalgam, which is distilled and afterwards made into gold and silver ingots. Silver and lead are also obtained from the ore, the latter being collected into a mass of some 20 tons, cupelled by a German furnace, and the bullion extracted and made into ingots. In 1878-79 the amount of ore reduced was 6,428 tons yielding 295 oz. of gold and 91,713 oz. of silver, at an expenditure of 85 per cent. Altogether the Government has spent 334,570 yen in erecting machinery, and the total loss during the ten years has been 240,126 yen. Upwards of 1,080 persons are employed, including 120 women for ore-picking. The daily output is 20 tons, and about the same quantity is reduced at the works, which consist of four smelting furnaces, one German cupelling furnace, six amalgam pans, ten stamps, two concentrating presses, two steam engines, one copper refinery, one assay room, and 12 coke kilns, and this plant is about to be still further increased by the present Superintendent.—(London) *Times*.

THE GOLD FIELDS OF WESTERN BENGAL.

MR. W. A. SHEPPARD writes in the *Englishman*, under date August 24th :—

In the year 1872, I issued a pamphlet on the important question of "searching for gold" and directed attention to the mineral bearing rocks of Western Bengal as likely to afford supplies of the precious metal ; since then, I have twice urged the public to move in the matter, and finally, on the 24th ultimo, I disseminated a circular carrying certain proposals on the same subject, which proposals have not been responded to, and will, therefore, be withdrawn at the end of the current month. As there are many persons residing in the districts of Western Bengal who may have opportunities afforded them of examining some of the localities covered by my remarks, I will, with your permission, furnish for their guidance—also for the information of tea planters residing in Assam and Cachar, where similar eruptive and metamorphic rocks occur—a brief summary of the modes of occurrence of metalliferous lodes and the names of the several kinds of rocks in which they are usually found, from notes jotted down while personally pursuing the interesting study, in the hope that by such means certain rock beds, hereafter described, may be carefully searched, and their hidden treasures reached and exhumed. In Australia, the Government of Victoria considered it worth their while to give large rewards to persons finding gold fields, also to supply individual prospectors with the means to go out and search for localities yielding the precious metal, and why a similar course of policy has not been obtained in India, where gold is so much needed to aid in restoring the equilibrium of exchange, has been the cause of much surprise ; and it is hoped that, when the so-called scientific frontier operations have been brought to a close, the Government of India will betake themselves to the more agreeable and sensible duties associated

with the arts of peace and render generous assistance to all who may desire to become benefactors of the country by promoting the opening up of its vast mineral resources.

Ores are of four kinds, and are thus classified; *1st*, mineralized with sulphur or sulphurets; *2nd*, mineralized with arsenic; *3rd*, mineralized with sulphur and arsenic; and *4th*, mineralised with saline substances.

Metals are always found as alloys, sulphurets, oxides of salts. Gold platinum, and columbian are found only as alloys. Silver, mercury, copper, iron, antimony, arsenic, and cobalt, in the four states; lead and zinc in the three last. Others, various, in two or three states. Tungsten, uranium, titanium, chromium and tantalium only as oxides.

VEINS.—The substance forming the outer coat of a vein is often intermixed, or forms layers alternating with the ore called matrix, gangue, or veinstone. Metallic veins are found chiefly in the oldest rocks, called primitive or transition, but they occur also in lower secondary rocks, and sometimes higher. Fissure or rake veins divide all the strata for unknown depths, sometimes perpendicularly but often obliquely; they are slips of equal width or chasms wider at top—those from east to west contain ores, and those from north to south at the intersections. Cross veins of quartz, and others of earthy matter, run north and south in all lengths and depths, and dislocate the metal lodes; they also contain galena or sulphuret of lead, iron, ochre, and arsenical cobalt, and when east and west, sulphuret of sliver. In Chili, the gold and copper lodes run nearly east and west, and the sliver every way. Mineral lodes are varied by rocks and strata through which they pass, and miners speculate accordingly. Metalliferous veins originate in cracks and crevices which extend to unknown depths; they occur mostly in primary or transition formations, in places where stratified rocks adjoin crystalline, for example, near the unction of granite, trap, gneiss, and quartz, with overlying schistose rocks. Veins in hard granite seldom afford useful metal, but in those of soft granite and gneiss are found copper, tin, and lead. When veins in rocks are exposed to the atmosphere, their superficial appearance often indicates the metal they contain. When a vein has fluor spar, it is associated with metallic substances; a brown powder at the surface of a vein indicates iron and often tin, a pale yellow powder, lead, and a green colour the presence of copper.

Igneous rocks comprise granite, porphiritic granite, vein granite, protogene syenite, peogamite, porphyry, basalt, greenstone, serpentine, trachyte, and lava.

Metamorphic rocks underlie the fossiliferous series, the various members of them succeed each other without any apparent regularity, and frequently alternate with one another; they are stratified, jointed, and with slaty cleavage, which, in most instances, is perfectly distinct from the cleavage arising from original bedding and deposition. Metallic veins of copper and lead occur in these rocks, as also gold, silver, antimony, and mercury; the principal are gneiss, hornblende, slate, mica slate, talcose slate, clay slate, chiastile slate, primary limestone, and quartz rocks.

GOLD.—Occurrence of. The rocks are metamorphic slates that have been crystallized by heat, and they are the talcose and argillaceous, that have been but imperfectly crystallized, rather than the mica schist and gneiss which are well crystallised. The veins of quartz which contain the gold occupy fissures through the slates and openings among the layers. The nearer that quartz is found to the igneous rock and place of irruption, the greater will be the probability that so heavy a metal as gold, or indeed any other metal, will be found with it. Accordingly, it is in the highest part of the auriferous country, indeed, in immediate contact, not with the schist, but with the trap rock itself, or with the gneiss, that gold has been found in Australia.

The auriferous ridges here (Australia) are chiefly composed of a vast mass of chlorite or quartziferous schist, a rock belonging to the primary or crystalline series of rocks, and here intimately associated with trap rock, lydian stone, ferruginous conglomerate, or old red sandstone and primary limestone, the basis of the whole being granite. The trappean conglomerate with imbedded quartz pebbles on the flanks of the granite range of Mount Cole ought to guide modern prospecting parties to the localities where gold may be found, and also the description of the country from thence eastward. At the upper sources of the Murray and of Tumut, the rocks consist of granite, schist, and quartz. The same may be said of the valley of the Tooma, where granite, trap rock, and schist are the rocks—stupendous gullies and ranges are the characteristic features.

The subject of the occurrence of gold in veins and masses is most obscure, but the general fact that they are most abundantly situated near the junction of the stratified and unstratified rocks, indicates their connexion with an igneous cause, and, in common with other veins, the two principles of simple injection and chemical segregation have, doubtless, operated in their production. "My search for gold in the matrix" (writes Sir Thomas Mitchell) "might have been limited on this principle to a very few localities, whereas the wide extent of the quartziferous schist, although only supplying auriferous deposits in the streams, was also to be ascertained. I have learned that gold is to be found in both localities, but under circumstances distinctly different. I believe it is useless to look for any prolific gold mine amid the schistose lamina whence the streams carry by abrasion small particles of gold; and that it is only where the occurrence of trap rock affords evidence of the action of disturbing forces, that we may look for gold or metallic ore in any great abundance. The occurrence of gold on the margin of the trap rock of the Canobolas, amongst unabraided fragments quarts and combined with ironstone, confirms me in these views, and has indeed partly suggested them; and when I consider the direction in which metalliferous veins have been found in the same district and the very remarkable contour of the surface where metallic ores and even pure copper may now be seen, I feel no hesitation in saying that it is very easy to distinguish the localities where the precious metal may be looked for in metallic veins from those where it is disseminated in small particles through extensive regions of territory. The "Indi" or Limestone river, is that source of the Murray nearest to Cape Howe and the eastern coast; it is characterized by the same rocks, at an elevation at which snow covers the country during many months of the year; the whole country abounds with springs and mountain torrents, and I have no doubt that, in the most elevated portion of our primary formations, the principal mineral riches of Australia will eventually be discovered. It will probably be there that gold and other minerals will be found in such abundance as may well deserve the most careful management."

SILVER.—Occurrence of.—The ores from which the silver of commerce is usually obtained are the vitreous silver, brittle or black silver ore, red silver ore, and horn silver. Besides these, silver is obtained in large quantities from galena (lead ore) and from different ores of copper. Some galenas are so rich in silver that the lead is neglected for the more precious metal. The metal occurs in rocks, of various ages, in gneiss and altered rocks in porphyry, trap, sandstone, limestone, and shales, and the sandstone may be as recent as the middle secondary. Silver ores are often associated with ores of lead, zinc, copper, cobalt, and antimony; and the usual gangue, or veinstone, is calc spar or quartz with, frequently, fluor spar, pearl spar, or heavy spar.

The Potasi mines in Buenos Ayres occur in a mountain of argillaceous shale whose summit is covered by a bed of argillaceous porphyry. The mines of Kongsberg occur in gneiss and hornblende slate in a gangue of calc spar. The ores of Hartz are mostly argentiferous copper pyrites and galena, yet the red silver, vitreous silver ore, brittle silver ore, and arsenical silver, occur. The rock intersected by the deposits is mostly an argillaceous shale. Carbonate of lime is the gangue, though sometimes quartz. In the Tyrol, sulphuret of silver, argentiferous grey copper, and mispickel silver, occur in a gangue of quartz in argillaceous schist. In Hungary, silver mines occur in syenite and hornblende porphyry in a gangue of quartz, often with calc spar. At Dauwin in Russia, it is found in argentiferous galena in a crystalline limestone, and at Altai they occur in silurian schists in the vicinity of porphyry, which also contain gold copper, and lead ores.

TIN ORE.—Occurs in veins in the crystalline rocks, granite, gneiss, and mica slate. The Cornwall veins mostly run east to west, the gangue is quartz with some chlorite. In the Ramgurh district native oxide of tin is found disseminated in gneiss; the ore is found in nodules of imperfect crystalline form, from a few grains to an ounce and upwards in weight, intermixed with gravel. The place where this tin occurs is elevated 1,500 feet above the level of the sea, about 100 yards in width, and of indefinite length.

LEAD.—Occurs in primary and transition rocks, except trap and serpentine, also in porphyry, syenite, the lowest sandstone and occasionally in coal-strata. The mountain limestone is the chief depository of lead ores. Of the presence of this ore, the principal indications are fragments of calc spar in the soil; the red colour of the soil on the surface arising from the ferruginous clay in which the lead is often imbedded, fragments of lead (gravel mineral) along with the crumbling magnesian limestones and dendritic specks distributed over the rocks, also the depression of a country or an elevation in a straight line or a peculiarity of vegetation in a lineal direction.

COPPER.—Is found in primary and transition rocks: lodes of copper are generally covered with brown ochre, friable quarts (gossam) with tin on one side and gossam on the other. The copper, in such case, is a bi-sulphuret, and the tin a peroxide. Sulphurets of iron, zinc, and lead abound in the lodes likewise. The sides of lodes are generally quartz, school, and friable rock.

Mercury occurs mostly in connexion with talcose and argillaceous shales or other stratified deposits, both of the most ancient and those of more recent date, including coal strata.

The north-western and western districts of Bengal, namely, the Sonthal Pergunnahs, Monghyr, Ramghur, and Chota Nagpore, are very largely represented, by metalliferous rocks. The Rajmahal Hills are composed chiefly of basalt, and adjoin the extensive crystalline beds, gneiss, and quartz, of the Ramghur district; immense mountain ranges of granite with bold and imposing peaks form the western boundary of that district. Schistose formations are also largely represented and are found invariably super-imposed on beds of either quartz or gneiss. It is known that in the vicinity of Deoghur (Sonthal Pergunnahs) silver, copper, lead, and iron mines exist, and that copper, tin, lead, mica, and iron deposits are largely distributed throughout Ramghur Division. The Toondee and Kurruckdyah Hills in the Ramghur Division, and the Curruckpore Hills in the Monghyr Division, offer very promising fields for exploration. Moreover, the entire country around Hazareebagh presents indications of the presence of mineral wealth, and I may add, by way of stimulus, that the only good specimen of gold on view in the Indian museum is a small nugget found a Jaspur in the Hazareebagh district.

FORESTRY.

THE influence of man upon climate has been a favourable subject of late years, and it is now well known that by cutting down forests and draining the soil man can materially change the climate of a country. Some recent experiments conducted in Germany confirm this belief by showing the extent to which woods will affect the rainfall. Two observatories were established for the purpose of comparison—one over a clump of pine trees forty feet high, and the other over a bare sandy plain about three hundred and thirty yards from the wood. Both of the observatories were built at the same height from the ground. Twelve months' observation showed that of the total rainfall within that period ten per cent. more rain fell over the trees than over the bare land, distant three hundred yards from them. Further, the air over the wood was found during the whole year of observation to be charged with aqueous vapour to the extent of ten per cent. in excess of the air over the barren open soil. The ground, too, under the trees retained far more water than the exposed earth, the evaporation from the surface, thanks to its shade of trees and moss, being only one-sixth of that outside their friendly shelter. These results are valuable in that they point out a possible means of improving the condition of sterile tracts, *i.e.*, by the planting of trees.

THE ever-increasing destruction of Russian forests is fast becoming, says a Russian paper, one of the leading questions of the day. Droughts, and their necessary result—famine—are now denuding more than one hitherto fertile and wealthy district of Russia. The Government has at last opened its eyes, and repressive measures are being adopted. The Department of Public Domains sent several officials to investigate and report upon the extent of the mischief done; and now that the reports are all in, it is issuing new statutes which must put an end to greedy speculation, even on private domains and among forest owners. It has also adopted the following severe measures to prevent depredations in Government forest:—"No one, unless he is furnished with a due permit, whether he be on foot or in a vehicle, is allowed to enter a State forest. By trespassing on the forbidden ground, he makes himself liable to the severest punishment, even though he can prove that he had no criminal intentions; the cutting of wood, or even the simple damaging of a tree, is to be henceforth classified as theft in the first degree—burglary—and subject to the severest penalty permitted by law." It is quite time, says the authority quoted, that the authorities sought a remedy for the evil. The hills are stripped of their vegetation, the forests decimated, the springs are fast drying up, and wealth disappears.

WE have received a copy of the Forest Administration Report of the Central Provinces. The area of the Government Forests is as follows:—

	Acres.
1st Class Reserves	16,22,454
2nd " "	107,82,991
Unreserved Forests	1,44,416
Total ...	1,25,49,861

While attention is paid to ancient forests, we are pleased to note that large extensions are made in the direction of putting out young plantations. During the year under notice 282 acres were sown with teak, 106 acres with teak and bamboo, and 540 with bamboo alone. Extensive bamboo nurseries were also made to supply stock for future plantings. Prosecutions for breaches of the forest laws were very numerous, having amounted to 1,408 cases, as against 367 in the preceding year. In 92·5 per cent. of these cases convictions were obtained, which points to carefully got-up cases. The financial statement shows well. The total expenditure amounted to Rs. 5,22,573, while the income from all sources aggregated Rs. 10,06,723, leaving a surplus of Rs. 4,84,150 as against Rs. 4,59,147 during 1878-79. We observe the officers of the department have been trying their hand at farming with the usual result. It is admitted very naïvely that "the crop raised nearly covered the expenditure." We wonder how long ordinary cultivators could continue to keep themselves and their families by crops which "nearly covered the expenditure." It is little wonder that the expenditure was not covered when we read that the produce was 252lbs., and grain 210lbs. per acre. It is scarcely worth while for these officers to waste time in experiments of a nature in which they are sure to be worsted by the common cultivator.

THE Chief Commissioner of Burmah observes, in a recent official paper, that the early enactment of a Forest law for British Burmah is very desirable. A draft bill was circulated in the province some while ago, and full opinions on it obtained from civil and forest officers, in accordance with which the Bill was revised by the Inspector-General of Forests. It was then thoroughly discussed by a special committee presided over by the Chief Commissioner, and in its amended form has been submitted to the Government of India. The measure, if passed into law, is likely, says the Chief Commissioner, "to introduce into forest administration a precision and definiteness—which are at present somewhat lacking—and generally to be of much benefit, both to the people and to the officers concerned in the administration of the law."

LAST year, the area of reserved forests in Assam was increased during the year by 32 square miles and 200 acres, raising the total at the close of the year, to 2,015 square miles. The additions were in the Goalpara and Tezpur divisions. An area of 108·16 square miles, in the Kamrup, Darrang, and Sibsagar districts, is under settlement as reserves, and the Forest Settlement Officers are now conducting their enquiry into rights in the area gazetted. Besides these, about 145 square miles, in Goalpara, Kamrup, Sibsagar, and Darrang, have been inspected and proposed for settlement as reserved forests. The work of completing the selection and demarcation of the Government forest property in the province is thus being vigorously pushed on, and the progress made during the year is satisfactory.

JHUMING has been kept well in check, in Assam, during last year. In the Nambar forest, in Sibsagar, it was completely excluded, and in Cachar, where, owing to the habits of the people, it is difficult to keep them under sufficient control, great success was attained. The Chief Commissioner has recently called the Deputy Commissioner's attention to the question in this district, and has asked for a report on the sufficiency of the areas allowed to the jhuming tribes in the neighbourhood of the reserves. Sir Steuart Bayley is, we fear, too scrupulous on the point of possibly injuring or inconveniencing itinerant cultivators. Deliberate destruction of useful timber should be made a subject of severe penalty, such as would prove exemplary in its enforcement. In Cachar, which is at present the one district where the operations of the Forest Department proper are remunerative, and on which the teeming population of the Surma Valley and the adjacent districts of Bengal mainly depend for their supply of timber and forest produce, proper conservancy is of the highest importance.

DR. BRANDIS ON "THE DISTRIBUTION OF FORESTS IN INDIA."

FEW, we think, would deny the value or importance of the lecture delivered recently in the rooms of the United Service Institute, (Simla) by Dr. Brandis, the able chief of the Forest Department in India. Dr. Brandis' discourse was profusely illustrated with various specimens of wood, in their varied phases; taken from the time, say, a tree was a mere infant; after, a stripling, up to its attainment of the position of a 'full-grown.' The lecturer sketched the birth and growth of trees, particular kinds and in a general way; how they looked when they attained the first 'ring,' or say, as 'two-year olds;' and what they seemed at the not very patriarchal age, arborically, of two hundred years or so. Most curious and intensely interesting it must have been to many present to note the beautiful, fantastic, and singularly diversified surfaces of samples exhibited of various trees, especially two, severed off at the base; how one, the *teak*, "that most useful, honest, and valuable tree," had only accomplished a diameter of eighteen inches at the base, at the tolerably mature age of ninety-five years; then came the *deodar*, a more promising member of arborical society, which, as to growth, nearly matched its rival on attaining its 56th year, or thereabouts. There were various other samples of woods fashioned into small blocks, which a young forester handed round to the doctor's hearers, and very curious and very interesting were many of these specimens. The great home of the *teak* tree is Burmah, where it flourishes. Several instructive features, in connection with the soil and temperature in which this tree thrives, and the conditions under which it does not, were pointed out. The *deodar* seemed more in favor with the lecturer and those listening to him too, and he handled its nether extremity, the sample block of the tree's base, with the affectionate manipulation that one would expect to see bestowed on a promising bantling. The tree is found in all soils, or, more correctly, thrives in sandstone, limestone, everywhere, save in the soft alluvial soil so favourable to many orders of vegetation. The trade statistics of the wood export were exhibited, and formed not altogether the least attractive of Dr. Brandis' illustrations. A great variety of foliage of trees of home and indigenous families, was exhibited; likewise varieties of acorn fruit, of that comparatively "useless tree" the Himalaya oak, a block of which was amongst the larger specimens displayed: it was sawn off at a diameter apparently of about fifteen inches, or when it was calculated to have counted some two hundred winters. It may be interesting to some persons to know the comparative production as regards indigenous trees in India and in Europe. Thus, taking, say Great Britain, France, Germany, Russia, and Turkey, with some few other continental countries, it is pretty accurately calculated that there are, in their whole extent, some 600 varieties of arboriculture; while in India, having about the same area as the several countries enumerated, there are four thousand varieties. One of the most formidable foes that the forest department has to fight against in India is fire—perennial, destructive, devastating fires which denude almost incredibly large areas every year. But their recurrence has been, or is likely to be, considerably checked, if not to be altogether stopped by operations of the Forest department, now being perfected; and these arrangements are meant also to provide against the wholesale forest denudation existing from causes unconnected with fires

Perhaps some slight conception of the magnitude of the descriptive history of arboriculture may be arrived at from the simple fact that, after an hour's uninterrupted and unusually agreeable converse, the lecturer had sketched, and that admittedly incompletely, the domestic history of *two* only, out of the formidable family of four thousand indigenous trees! Dr. Crawford, Surgeon-General, who presided, happily observed, in his concluding address, the essayist had "put tongues in the trees," which, if not an originaly *bon mot*, was at an rate most appropriate.—*C. and M. Gazette.*

RECLAMATION OF WASTE LANDS.

ONE of the most valuable branches of modern enterprise is the reclaiming of waste lands, and the last Paris Exhibition contained, in the division devoted to Forestry, some interesting relief plans of works and plantations, by means of which the great waste dunes lying south of the mouths of the Gironde had been redeemed and brought under cultivation. The solidification of dunes by means of the growth of grass and planting of trees, is a work of much difficulty. The problem is to "fix" the sand hills and sand heaps. The work must be very gradual. A whole series of dunes is marked out, the line being drawn as nearly as possible over their crests. The parting off is effected by means of a strong fencing over the crest of the dunes towards which the smaller cross fences lean, herring-bone fashion. The result of this construction is the accumulation of ever-increasing masses of sand in the places thus protected, which eventually form a bulwark for the space behind, against the rush of the waves. The area thus enclosed is first planted with meadow grass, and next with coniferous trees, the latter being at first protected against sand-drifts by means of brushwood. Sedges, broom, and esparto grass have also been found useful for first cultivation. The dunes lie partly below the level of the sea, and the soil reclaimed already amounts to many thousand acres. Where, a century ago, there was only a desolate and marshy expanse, the eye now ranges over splendid forests in which deciduous trees are growing up in ever-increasing number; while prosperous villages and large herds of cattle and gardens and vineyards, are dotted all over a tract of cultivated country which was formerly a silent, dreary waste. Perhaps, in time, those dreary wastes between Paris and the coast, which produce so depressing an effect on the traveller, and remind the Anglo-Indian of the too familiar sandy wastes of the land he has left may be turned also into a beautiful wooded district. And in this way civilization may compensate for its devastation of some of the loveliest parts of Europe, by creating beauty where there was desolation before. The experience gained by the French Department of Woods and Forests, with regard to the acclimitization of foreign, and especially of trans-oceanic forest trees, is particularly valuable. The blue gum-tree imported from Australia prospers in the south of France; and by its plantation at the mouth of the Var, the marshes surrounding it have been drained, and the fevers formerly so prevalent there have been banished. The trees prosper wonderfully in Algiers, the diameter of the trunk attaining to one foot in less than fifteen years. But the wood is white, light, and brittle; and is not to be compared to the durable ship timber which the same tree produces in Australia. It is the same with the American oak, which thrives in poor soil, grows rapidly, and forms beautiful tops of foliage. But the wood is poor and the bark contains less tannin than that of the European oaks. These trees consequently, can only be planted in certain cases—principally to prepare the ground for better kinds. Very valuable relief plans were also exhibited of places where afforestation had checked recurring floods. In 1868 there was a broad desolate gorge near the Barallounette in the Basses-Alpes, a rocky sterile tract of rubble below the Torrent du Bourget. The hollow is now half-filled up by the construction of high dams of stone; trees, and bushes, and turf have been planted and thrive to the very edge of the gorge, and what was a fierce forest torrent has been reduced to a steady quiet brook, and the valley has never since been desolated by inundation.—*Pioneer.*

AFFORESTATION IN JAPAN.

UNQUESTIONABLY afforestation is of great importance in Japan, where the active demand which has of late years arisen for timber is having the effect of rapidly denuding of trees very large tracts of country. On several occasions we have urged upon the authorities the necessity of protecting the forests and providing for future requirements. We propose to further stimulate their energies by reference to what has been successfully accomplished in Hong-Kong where afforestation is evidently conducted upon scientific principles, and therefore with due regard to the circumstances of soil and climate. In a recent Hong-Kong *Gazette* appears the report of the Superintendent of Gardens and Plantations, on Afforestation in the colony. From this document we learn that there are ten Government nurseries situated in Hong-Kong and on the Kowloon peninsula, which comprise about 150,000 two-year old trees, and small seedlings raised this year to supply about 250,000 trees for planting in 1881. The 150,000 two-year old trees now in the nurseries will be nearly all planted during the next two months; 60,000 trees have already been planted this year, and sites sown on the hills, where the seedlings will remain, for 60,000 more, which will make a total for this year's work of 270,000 trees covering an area of 245 acres. In addition to *Pinus sinensis*, which has hitherto been chiefly used for the endowment of the hills with forest vegetation, seeds of several of the indigenous trees of other kinds, such as the oaks, tallow tree, &c., several species of *Eucalypti*, and other Australian trees, and the Japanese *Pinus Massoniana*, have been sown in the nurseries, so as to afford more variety to the future plantations, as probably many kinds of trees not yet used may be found to succeed, and render the plantations more valuable and beautiful in years to come. If the experiment which is being tried of sowing the seeds *in situ* proves successful, which it promises well to do, the cost of afforestation of the Island will be much reduced and the operations greatly accelerated. The Superintendent estimates that with the like sum of $7,680 which was granted for each of the last two years, he will be able to sow, *in situ*, seeds to cover 600 acres, that is, about four or five times as large an area as could be accomplished by rearing trees in nurseries and then transplanting. Mr. Ford is also of opinion that the work of afforestation can no doubt, be greatly advanced by the co-operation of Chinese, who would, if suitable encouragement be offered by the Government, undertake to plant large areas for the return of being allowed to use the thinnings of the trees, under certain regulations, for a certain number of years, say 15, when the plantations might revert to the Government, or be leased for an extended period, under such a regulation, or modification of it, as Clause No. 23 of the Mauritius Ordinance No. 12 of 1872. Three or four of the small market gardeners at Kowloon have expressed themselves willing to plant 100,000 trees next year under such an arrangement as the above, and one of the chief contractors in Hong-Kong says that he would like to plant trees if the benefit could be secured to him for 50 years. With such results before them the Government of Japan should lose no time in following the example of nearly every civilized community.—*Japan Weekly Mail.*

GARDEN.

THE London correspondent of the *Manchester Guardian* learns that the scheme for a complete botanical survey of India, for which subscriptions in aid of a prospective Government grant are being raised, both in India and in the United Kingdom, is likely to be so extended as to include geology and zoology. The general conduct of the expedition, as well as the superintendence of the special botanical department of it, will be entrusted to Mr. George King, of the Botanical Gardens, Calcutta, should his health permit him to travel over India for ten years, before which time, at the very earliest, the work of the survey will not be completed. With Mr. King will probably be associated several *savants*, both British and Indian. The details of this part of the scheme have not yet been settled.

WE notice that the Shillong Experimental Farm was made over to the charge of the Forest Department during the year, as a nursery of fruit-trees. Sir Steuart Bayley hopes that, in their hands this may become a useful centre for the diffusion of European fruits, many of which would probably do well, through the Khasi and Jaintia Hills.

AN experiment in the cultivation of the Carob seed is to be tried in the Botanical Gardens, Calcutta, under the orders of the local Government. On the requisition of the Government of Bengal, some samples of those seeds have been sent down by the North-Western Provinces, with the necessary instructions for sowing. Autumn is the proper season for growing this plant.

A BOOK on tropical plants by Baron Fred. Von Mueller, is advertised by the Superintendent of Government Printing, Calcutta, in a recent *Gazette*. The author is (or was, for he may have joined the majority) Curator of the Botanical Gardens at Melbourne.

A VERY useful catalogue of plants in the Botanical Gardens, at Bangalore, and its vicinity, has been prepared and published by Mr John Cameron, F.L.S., the zealous Superintendent of the Lal Bagh with a view to facilitate the interchange of plants with kindred institutions at home and abroad. Mr. Cameron justly remarks that "Bangalore is celebrated as one of the chief horticultural stations in India, and this circumstance is due to its geographical position, which commands a genial climate. But, independent of natural advantages, the British residents have done much to encourage horticulture by their influence and example. Useful plants and industrious habits have followed their footsteps, as is always the case in the march of civilization." An index of eighteen pages, containing upwards of 1,500 genera, is appended the catalogue.

THE latest accounts from the continent of Europe speak favorably of the prospects of the grape harvest. The month of October is the one for gathering in the produce of the vine, and those who have once witnessed the process, will readily recall to mind the bright, happy, bronzed faces of the reapers, young and old; as different in their bearing, as they are in their costumes, to the English farm labourer. The ravages of the *Phylloxera*, which threatened to devastate the vines, have been stayed, and the weather has been favorable to the continental harvest, as it has been to the English; and the scientific wine makers pronounce the chemical properties of the new grapes to be satisfactory.

THE Americans having discovered that their delicious apples, the "New Town Pippins" do not command so good a price in the English market as they ought to do, on account of the bad condition they arrive in, have as usual, set their busy brains to work, to discover something that shall preserve the fruit. They have found what they required, and find that three or four folds of paper steeped in salicylic acid solution, and afterwards dried, and wrapped round the apples preserve them perfectly. The

best preparation for the purpose is an alcoholic solution prepared from the strongest spirit. The system is cheap and efficacious, and some of our readers may like to try the experiment of preserving fresh fruit by this method.

FRENCH GRAPES IN CASHMERE.

THE growth of French grapes in Cashmere has proved a signal success. Major P. D. Henderson and Mr. Chapman of Umritsur, with whom the scheme originated—his Highness the Maharajah, by whom the scheme was adopted—and last but not least, Monsieur Ermens, by whom the scheme was so ably worked and carried out, all contributed their share towards bringing to a successful issue one of the best—if not the best—and most useful development of the resources of this famed and beautiful valley. Monsieur Ermens having been chosen by the *Société Horticole* to select the land for the planting of French grape cuttings, was not long in accomplishing the task allotted to him, although he had to surmount many difficulties before he adapted it to his plan. He had to cut regular terraces on the side of the hills, and also to make a canal run all along the tops of the vineyards, so as to keep up a regular and plentiful supply of water. In January 1877, he imported a lac of cuttings from Margaux and Chateau Y Quem. These were *Raisins Blancs* or white grapes, for Sauterne, and Chateau Y Quem. For Bordeaux wine he imported four kinds of *Raisins Rouges* or black grapes. These he planted in beautiful order on no less than a hundred terraces, 100 × 20ft. These terraces flank a road eight yards wide, which runs the whole breadth of the garden, and which is hedged with plants bearing two hundred varieties of table grapes. The walls of the terraces also have table grape vines creeping on them. When these grape cuttings were first planted, the Maharajah, who showed great interest in the matter, requested Monsieur Ermens to give him an idea of the crop he expected. Monsieur Ermens said that after three years he would guarantee three clusters per plant, after four years six, after five years ten, after six years fourteen, and after seven years only, a full crop. Matters have, however, turned out very much more successful, and the crop which has just been gathered has far exceeded Monsieur Ermens' expectations. On some trees there were as many as thirty and forty clusters. Some time ago the blight among the grapes in Europe, known as Phylloxera was disastrous, and the Ministry in France communicated with Monsieur Ermens through their Consul-General in Calcutta with the view of ascertaining the state of the plants in India. Monsieur Ermens in his reply, which is published in the *Revenue Horticole* of July last, gives some very interesting and important facts. He says that there are two kinds of grapes in India. These are classed under the following names:—Opimam and Kawauree. The Opimam is a magnificent white grape: very sweet, grows in large clusters, and the fruit is scattered, not close together, on the bunch. The Kawauree is a beautiful red grape, not so sweet, but larger than the Opimam and with the fruit close and in large clusters. In Cashmere the vines trail on the poplars and sometimes grow over sixty yards in height. Although wild, they produce abundantly. These grape vines, in the hands of French cultivators, would bear magnificent fruit. Although not of *première qualité* for wine making, they are vigorous and thus most suitable for grafting with the delicate plants of Europe. Monsieur Ermens informed the Maharajah of the communication he had received, and his Highness at once requested him to despatch two hundred plants to France; and also showed his good will, stating that for future supplies he would give his share by defraying the expense of conveyance from Cashmere, to Wazirabad Railway Station. The cost of the transit of these packages to France is only 12 annas per lb. In sending the grapes Monsieur Ermens gave some very useful hints regarding the future export of cuttings from India for grafting purposes in France. The best means of sending them is not by post, but by coolies to Lahore, from thence by railway to Bombay, and on by steamer to France. The best time to send them is October, so that they arrive in good temperature. The best and most economical way of increasing the cuttings on arrival in France is to first plant them in a hot-house; from each and every eye in the cuttings sent, healthy and vigorous plants can thus be raised. Monsieur Ermens then speaks of the different methods of packing grape cuttings for import to India. He says this is a most important item, and the various ways of packing having all been tested by him, he cannot but speak with great positiveness on this subject.

First.—Vine cuttings packed in sawdust. Those have all died.

Secondly.—In damp moss. This is equally bad, for all the cuttings take root and thus lose sap. This injures all prospects of a crop, even if the plants reach and attain any growth at all.

Thirdly.—Packed in dry moss—favourable result, but also a little risky.

Fourthly.—Cuttings in powdered charcoal—the *best* manner of packing. The charcoal absorbs the dampness, at the same time maintains temperature and requisite moisture, preserving the whole plant.

Regarding the export of cuttings from India to Europe, Monsieur Ermens thinks the best time to send them is from November to March. In dry cases, they can travel safely. Tin boxes invariably injure the seeds.

The fruit plants sent out, which comprised apples, pears, nectarines, and plums, were packed in earth and did not only reach Cashmere safely, but were sent on to Gilghit where they were planted by Major Biddulph, and are now luxuriant trees. The cuttings, when they reached here, were put into running water for forty-eight hours and then planted in the nursery stores. From thence good healthy cuttings were taken to the terraces. Monsieur Ermens got his table grape cuttings from Antonne Bepon and M. Auguste Roy. M. Roy also furnished the other fruit trees, viz., apples, pears, plums, &c.

The wine grape cuttings were from M. Paul Skavenski of Margang M. Skavenski is the Manager of Chateau Brown Cantenne and various other extensive properties in Medoc. In order to get the cuttings into India by January and February, M. Skavenski had to cut them in the depth of winter instead of the usual time in March. He also supplied the Bordeaux cuttings, and even procured the valuable ones of Chateau Y Queen from the Marquis du Sur Sulluce. The Macon wine cuttings were furnished by M. Pulliat. With the generous purse of the Maharajah to support his undertaking, and with the knowledge Monsieur Ermens possesses of these matters, it is no wonder that such a grand success has been achieved. The cutting of the first cluster of French grapes in Cashmere was, under the circumstances, a great event. But, in consequence of the bad news from Candahar and the disaster to General Burrows' force, both the Maharajah and the Political Officer, Mr. Henney, were absent. The gentlemen who did assemble to witness it, took a lively interest in it, however, and among the matters of importance to record on that auspicious occasion is the fact that sparkling wine made from Cashmere wild grapes was drunk.

The machinery hitherto used for making the wine above-mentioned is only on a very small scale, but the new machinery, which has just been received, will enable Monsieur Ermens to manufacture what he desires to do, to his heart's content. The Maharajah is laying out a good deal of money on the buildings of the manufactory, which in a short time will form in itself a pretty village and also a great industry for the people in Cashmere. Cuttings will be given to all the surrounding zemindars, who will plant and sell their fruit to the wine manufactory, getting more profit than they would do by the sale of rice and grain.

At Rugonathpore, where Monsieur Ermens lives, sauterne is being made from the French grapes grown there. The *modus operandi* is pure and simple. The best wine is made from unpressed grapes. After the fruit is gathered it is brought to the manufactory. The process of picking here goes on, and after it is finished the grapes are taken to the pulping house and pulped. The pulping process is a delicate one, as great care has to be taken not to bruise the seed, which contain oil that would retard the process of fermentation, in addition to according a bad flavour to the wine. From the pulper, the juice and pulp are both transferred into baskets which strain only the natural juice (without pressing) into an immense wooden vat built on an incline, so as to run the contents into another tub or vessel, from which they are taken and placed in casks in sufficient quantities to permit fermentation taking place without any loss of liquor. The casks are all kept open until fermentation is over; they are then filled and closed. The time for opening them again is determined according to the temperature and climate.

The above is a description of the first quality of wine, *i.e.*, from the juice of grapes without any casks pressing whatever. The liquor goes direct to the casks after the pressing process is over. To show that no wastage whatever is incurred, it is well to mention that after being pressed for 2nd quality wine, the pulp is placed in casks of clear water, and after fermentation the liquor is distilled for the produce of pulp brandy *eau de vie du Mar.*

In a year or two, Monsieur Ermens purposes to send table grapes—packed in clusters similar to those now so largely exported from France to England and America—to all the principal towns in India.—*Cor., Bombay Gazette.*

THE CULTURE OF THE GARDEN RANUNCULUS.

THE numerous varieties of the garden ranunculus are all the offspring, by selection, of the species known to botanists as Ranunculus asiaticus. They do not engage the attention of florists now so much as they did a generation or more back, though why this is so would be difficult to say. The marvellous beauty and symmetry of the flowers are in no way lessened, and their culture has not become more difficult. We presume the immense variety of flowers that has been introduced during the last twenty-five or thirty years, many of which cost less both to buy and cultivate, has operated to bring about the partial neglect of these most beautiful ranunculi, as well as many other old-fashioned things. There is, however, an occasional indication of a revival of interest in these fine old flowers, to be met with in gardens, which is very gratifying to see.

The culture of garden ranunculus in past times, was made somewhat of a mystery by the old florists. Those who excelled in their culture maintained that their success was due solely to the compost they made use of; and they endeavoured by every means to prevent their neighbours from getting a knowledge of the component parts of this compost, and of the relative proportion of the different parts and the manner of mixing them. But all of them made one ingredient the base of the compost, and that ingredient was the best turfy loam they could possibly obtain. This was usually cut from some piece of rich meadow, and laid on the surface of the ground loosely in the beginning of winter, for the purpose of having it exposed to frost, which had the double benefit of driving the dormant worm out of the sod to greater depths for better protection from cold, and also

the ameliorating effect on the texture of the soil which frost only can give. To such soil as this, after it has been stacked for a year, a fourth part may be added of horse or cow manure after it has been mellowed by turning it over frequently. If the soil should be inclined to heaviness, mix some sharp sea or river sand with it, and thoroughly incorporate the whole together. If possible, a moderately moist and shady position should be chosen for the bed in which the roots are to be grown, but avoid a wet bottom. In that case, the bed should be raised above the surface level, so as to insure the thorough drainage of all superfluous water. The practice of the old florists was to excavate the whole of the old soil, and wheel it away, filling up annually the space thus excavated with new compost. No doubt this should ensure complete success, but we do not consider it in any degree necessary, except where the soil is apt to become surcharged with moisture, and thereby deteriorated. In that case, we should certainly say renew the soil annually, but in no other would anything but partial renewal be necessary.

The time of planting may be any time from October to April, at intervals, so as to secure a good succession of flowers from spring till autumn. The roots may be planted at from 5 to 9 inches apart each way, according to the strength of the tubers and dry weather; and a dry state of the ground should always be chosen for the work of planting.—*N. B. Agriculturist.*

TEA.

THE China tea crop is said to be 20,000,000lbs. short, and the reports from Indian tea districts are somewhat unfavourable. "Unreasonable cold, and heavy rains have interfered with the growth of the leaf, and also with the manufacture."

WE extract the following from Messrs. Marsden and Walker's monthly Indian Tea Report for September, to hand by the last mail:—

A large trade has been done during the past month, and prices have, under the pressure of the quantity offered, gradually given way for all kinds except teas under 10*d.* We quote a fall of 2*d.* to 3*d.* on Pekoes and Broken Pekoes over 2*s.* Medium kinds have declined 1*d.* to 2*d.*, but the lowest grades of Pekoes, say from 1*s.* to 1*s.* 2*d.*, remain unchanged. Fine Pekoe Souchongs have declined fully 1*d.*, while inferior kinds from 10*d.* to 11*d.* have been steady throughout. Darjeeling teas of good quality have not been affected in price, and command high rates. Since the close of the month the auctions have become flat, and prices are further drooping, which would seem to arise from the very heavy auctions (averaging 3,600 packages per day), and not from any want of demand from the country. Deliveries for the month have not been so heavy for eighteen months; Imports are unusually high, being only exceeded in October 1877. Bank Rate 2½ per cent. September Public Sales comprised 52,750 packages, against 45,100 packages in 1879.

THE efforts to introduce the culture of the tea-plant into America do not apparently meet with unanimous approval. It is alleged that there is nothing startling in the statement made by the Commissioner of Agriculture that tea can be produced in the Southern States, but what the tea itself will amount to when tested by the palate and digestion, remains to be proved. Tea, like tobacco, varies greatly according to soil and climate; the seed from some of the most fragrant and harmless Cuban tobaccos has been planted in various parts of the United States and yielded leaves larger and more beautiful than ever were seen in the West Indies; but in most cases the odour is execrable and the proportion of nicotine several times greater than in the Cuban leaf. Occasional tea plants have been seen in the South for years, but to experts in tea a single swallow of the infusion prepared from these plants has been remembered, it is said, as long and unfavourably as a whiff of a full flavoured Louisiana or Michigan cigar. Our informant adds that "as only a little of the best imported tea can be taken with safety, the prospect of the American market being flooded with native teas from all sorts of soils is not a pleasant one to contemplate, for our national habit of disguising tea in sugar and milk makes it probable that in the event of lively American production millions of digestions and nervous systems will be ruined by the terribly astringent and stimulating properties of the native leaf. The probability of successful tea culture, therefore, cannot be regarded with unmixed satisfaction. The only safeguard of the private consumer will be in taking his beverage in Chinese fashion—that is, without sugar or milk. Even now this habit, easily learned and never afterward willingly abandoned, would drive out of the market three-quarters of the vile mixtures sold and swallowed as tea." If the opinion of the writer we quote from is at all prevalent in the United States, it is very evident that China and Japan have little to fear from the competition of American grown tea. But, as will be seen from our leading article on the subject, we are not of opinion that tea as an industry will succeed in America.

THE English market is generally so overstocked with Indian teas, that planters are driven to seek other markets for the rapidly increasing produce of Indian tea gardens. Australia now promises sooner or later a large demand for the pure article supplied from India; but the countries across our frontiers should afford an almost inexhaustible demand, if the kind of tea most in demand in those parts can be turned out by Indian growers. Mr. O'Connor's recent reports have shown how large a quantity of Chinese tea (rubbish, as much of it is) find its way *through* India to Central Asia; and it is only necessary for the Government of India to take decided action, to promote arrangements for supplying, with Indian tea, the vast demand that already exists in Tibet. In that as yet little known country, tea is almost universally imported in the form of bricks, and is used as a currency as well as a beverage. Certain kinds of brick tea form the principle money of Tibetan, not however reckoned by weight but by the brick; the weight of which, and presumably the quality, is more or less constant. Thus a sword may be worth three bricks, or a horse may be worth twenty bales of bricks, the bale containing four bricks. The price of brick tea per lb. avoirdupois runs at Lhassa from six to nine annas per pound for second quality, and nine to twelve annas per pound for better qualities. The tea is sown in hides, with the herring-bone stitch. Nothing can of course be done till the prohibition against the import of Indian teas into Tibet is removed through the action of Government. But the Kumaon and Assam planters should exert united action in moving Government in a direction of such vital importance to their interests.

AMONG the general indications of returning trade, at home, is the demand for Indian tea shares, and a growing interest in other products, such as tobacco. Large as it is, the Indian tea trade with Europe is only a faction of the China traffic. There is, therefore, a good deal of ground to be occupied in the West; but the principal field is in Australasia, where, unfortunately, owing to the nefarious tricks of Chinese dealers, and the bungling of Indian agents, Indian tea enjoys as indifferent a reputation as Manchester clay-cotton does in Canton. The first step to an improved trade lies in the prevention of imposture. As for the second product mentioned, it is very well known that tobacco has satisfied all the tests of the experimental stage. Only capitalists, careful growers, and skilled curers are required. The reports submitted to the Madras and other Governments, and the blue books written on the subject, by Mr. O'Connor, establish this fact beyond doubt. We also know that Burmah specimens sent to London dealers have been pronounced by them to be equal, if not superior, to the best produce of Havana or Manilla.

THE unsatisfactory state of the tea market during 1879-80 is seen in the fewer number of coolie labourers imported under the provisions of the Emigration Act into Assam. From the report issued by the Chief Commissioner, it appears that in 1879 only 34,712 coolies were imported against 43,061 in 1878, and 31,897 in 1877. This great decrease is certainly in a measure due to a difficulty in inducing labourers to emigrate from the plains, in consequence of the good harvests and cheapness of food. But the main cause is to be found in the fall in the price of tea. Every garden has been worked in the most economical manner, and as the price of labour has risen, instead of diminishing, there has been a natural tendency to restrict importations as far as possible. The Chief Commissioner, however, does not take a gloomy view of the future of tea cultivation in Assam. He hopes that the ominous signs of the past season will pass away, without leading to any permanent contraction of the operations of this most important industry. It is improbable, however, that tea cultivation will extend at the rapid rate of the last few years. The low price of tea, and the small returns of existing companies, will check the eagerness of speculators. Much of the best land has already been taken up, and sites for gardens, otherwise good, are at present useless, in consequence of the badness of the communications. Sir Steuart Bayley well says that the most important measure which Government can adopt in furtherance of the tea interest is to improve the communications. A quick passenger service is greatly needed on the Brahmaputra. It appears hopeless to expect that private enterprise will supply this want, and the provincial funds at the disposal of the Assam Administration cannot meet the cost. The Government of India refused to help the struggling province in consequence of the financial pressure, and Sir Steuart Bayley is now in the cheerful position of one who hopes that something may turn up. He has applied for aid to the Lieutenant-Governor of Bengal, and in the interest of Bengal Sir Ashley Eden will doubtless cooperate in improving the communication on the great water highway of the two provinces.

THE subject of labor in Sylhet is discussed in the *Indian Tea Gazette*, No. 80, and attention is drawn to the fact, that the plantations in the southern districts of Sylhet have only 2,000 Act VII. coolies, out of a total of 20,000; and this is ascribed to the managers of those gardens having enticed the difference, say 18,000 men, from Cachar and the northern gardens of Sylhet. This is a sweeping charge. May not a more charitable and more correct explanation of the circumstance be found in the fact that Sylhet is one of the richest agricultural districts in the Assam Chief Commissionership, and that the south gardens being in proximity to the Tipperah Hills, are exceptionally well placed as to a class of local labor that does not object to enter into short engagements, under the ordinary Contract Act at present in force?

MR. POWER, the Deputy Commissioner of Lohardugga, in the Chota Nagpore Division, has lately suggested that tea-planters should try to persuade the ryots to cultivate tea on their uplands, and pay them a liberal price for the produce. The Commissioner of the Division, however, believes that such a system could never be worked with success, and the Lieutenant-Governor of Bengal is disposed to agree with him. There are at present twenty-three

tea gardens in the Lohardugga district, with an acreage of 434 under mature plants, and 1,185 under immature plants; the average yield per acre being, last year, 189lbs., and 248lbs. the year before. The outturn of last season was seriously affected by the long drought and hot winds which came before the rains. Both in the Lohardugga and Hazareebagh districts, a large number of plants were either much injured or wholly destroyed. Mr. Power says, with reference to the comparative failure of the tea industry in the district hitherto, that there has been "a want of experience in the mode of opening out and treating a garden." The planters, on their side, complain that the supply of labour is getting short; and the hands, just as they have learnt their work and are beginning to be usefull are tempted away by emigration agents. The Deputy Commissioner adds that "if any great extension of the tea industry takes place, tea planters will have to import labourers from other parts of the country, and the additional expense will counterbalance the only advantage they possess at present over gardens in Assam and other tea districts."

THE quantity of tea exported from China to the United Kingdom from the 1st June to the 18th September this year, was 98,060,027 lbs., as compared with 105,999,906 exported in the corresponding period of last year. The exports to America from China and Japan during the same period were 42,386,538lbs., as compared with 35,484,577lbs., last year.

THE Japan papers contain a translation of an article from a local vernacular on the propects of the Japanese tea trade. The writer takes a gloomy view of the future of the industry and gives the following as one of the principal causes of its decay. "Recently," says the writer, "some clever, but dishonest, people have taken to mixing the leaves of other plants with the tea prepared for foreign countries, the result being that Japanese teas have deteriorated in value, and Chinese and Indian teas have ruled the market. It may be urged that there are many who simply mix an inferior with a superior class of tea and then pass it off as superior tea only; but there are many others who mix such things as wisteria and honeysuckle leaves with the actual tea, and both foreign and native buyers, having become aware of this practice, declare they will purchase Japanese teas no longer."

The following on Java tea is from the Consular Report:— "The greater portion of 1879 production was prepared especially for the London Market, and shipped *viâ* Holland to that port: English rolling machinery has been introduced on several estates with satifactory results. The China plant is still the only species cultivated to any extent by Java planters; trials are being made with the Assam shrub, but as yet they are on too small a scale to warrant an official report.' The quantity of tea exported from Java for the year ending 30th June 1879, was 67,052 cases, or about 5,699,420lbs., against 86,208 cases or about 7,327,680lbs. for the twelve months ending 30th June 1878.

COFFEE.

WE see that the Directors of the Date Coffee Company announce that owing to the disturbed state of the country at Bussorah, and for other reasons, Mr. Mare, the company's engineer and manager, has, with the approval of the Board, made arrangements to manu facture at Kurrachee. Mr. Mare has secured the requisite premises at a cheaper rate than Mr. Henley calculated, and he stated that he is satisfied he can manufacture at a less cost than that estimated by Mr. Henley. The whole of the works are progressing rapidly, and the first consignment, the whole of which is sold, will probably arrive in November. The Directors are further in a position to state that every day the demand for the coffee increases. The change of the place of manufacture from Bussorah to Kurrachee will, no doubt, be equally satisfactory to the shareholders as it is to the directors; for the latter place is nearer England.

THE coffee exporting season in Ceylon closed on the 30th September, the exports during the season were 670,000 cwts., of which 620,000 cwts., were plantation, and the remaining 50,000 cwts. native coffee. The *Ceylon Observer* says that the exportation of native coffee is steadily on the decline.

A COMMISSION is not likely after all to go from Java to Ceylon to inquire into leaf disease. Mr. Moens has reported that at present there is very little to be learned there, apart from what has been published, and we now read in the *Straits Times*:—

"The permanent committee (in Java) in the matter of the coffee leaf disease has found that sending out a commission of 4 persons to Ceylon will cost thirty thousand guilders."

THE Samarang *Vaderland* of the 8th September indicates as follows the cause of the coffee disease:—

"A native coffee planter of many years' experience has informed us of his opinion that the coffee leaf disease is caused by the practice, very general of late, of using fresh stable manure too soon when planting coffee in holes dug for that purpose. In proof of his theory he points to an estate where there are splendid coffee trees from 30 to 40 years old which bear fruit abundantly and are free from disease. These trees, says our informant were planted by him, no manure whatever being used on the occasion. He does not believe in ascribing the disease to mere exhaustion of the soil."

COFFEE CULTIVATION IN TRAVANCORE AND COCHIN.

THE following table, illustrative of the state of coffee cultivation in Travancore, for the calendar year 1879, has been drawn up by the Dewan of that State:—

District.	Plantation.	Acres Total.	Approximate yield, in lbs.	Ave. yield in lbs. per acre of mature plants.
Thovallay ...	19	4.462	721,476	294
Colcolum ...	22	6,291	670,601	191
Velavencode ...	6	769	60.976	225
Nedoovengaud ...	12	4 055	246 708	126
Kottaracurray ...	17	6,816	891,362	114
Pathanapuram ...	1	6,400	33 600	336
Chenganore ...	1	450	33,600	336
Shencottah ...	5	793	32 384	64
Neyattencurray ...	1	229	12 000	150
Meenachel ...	28	6 329	508,089	257
Chenganacherry ...	9	1,211	195 014	281
Total ...	121	37,805	2,905,810	192

There are mature plants on 15,084 acres, and immature plants on 2,429 acres. The remaining 20,292 acres have been taken up for planting, but have not yet been planted.

In the state of Cochin there were 19 plantations last year in the Chittoor district, at an elevation of about 3,000 feet, and covering an area of 8,492 acres, of which 1,256 acres were occupied by mature, and 658 by immature plants, leaving 6,578 acres to be planted. The approximate yield was 378,684 lbs., or an average yield of 301½ lbs. per acre of mature plants.

MEMORANDUM ON FROST AS IT APPEARS ON COFFEE ESTATES.

FROM the tenor of reports which reach us from time to time, we gather that a somewhat general misapprehension exists as to the causes of frost on coffee estates, with a consequent misdirection of the efforts made to counteract it. With a view, therefore, to a more correct appreciation of the causes of frost and the appropriate remedies for it, we submit, for the information of those who have not hitherto given the matter their particular attention, the following remarks embodying what we believe to be the true theory.

We propose to consider:—

1. What frost is *not* caused by.
2. " " is due to.
3. The remedies.

First.—Frost is *not* caused by dampness of the ground or moisture in the atmosphere. It is no doubt true that frost generally attacks coffee grown on flats or in hollows. It is equally true that it is in such situations that damp ground and aqueous vapour are found, but it does *not* follow that the former is the effect of the latter. On the contrary, the presence of aqueous vapour has a direct and powerful effect in preventing frost, and as a consequence any effort directed to the reduction of the amount of aqueous vapour held in suspension, such as deep draining, &c., with a view to the prevention of frost, must fail of the desired effect. Draining flats and swampy ground may and does benefit the trees in other ways, but as a preventative of frost, it is not even neutral; it positively tends to an opposite result.

Secondly—Frost is an effect of chilling by radiation. In other words, the ground, the trees, and the atmosphere by which they are surrounded radiate or give off, during the night, the heat which they have absorbed during the day, until, by a series of actions and re-actions, which will be explained further on, the trees are chilled to a point at which frost is formed. The formation of dew is an earlier stage of the same progressive lowering of temperature.

Certain conditions are essential to the full development of this radiative energy. They are princi pally as folllows:—

A clear sky free from clouds.

A dry atmosphere free from aqueous vapour.

A perfectly still atmosphere.

The absence of any one of these conditions will generally be sufficient to check radiation and prevent the temperature falling to the point at which frost is formed.

We have not personally had many opportunites of inspecting cases of rost-bitten coffee, but we believe the following are facts:—

1. Frost occurs only on bright clear nights when the sky is free from clouds.
2. Frost occurs only during dry weather.
3. " " when there is no wind.

4. Frost only attacks coffee on flats and in hollows; it does *not* occur on slopes or on hill-sides except sometimes just at the bottom.

5. Frost is apparently formed near dawn.

6. High-topped coffee is less liable to be frost-bitten than low-topped, other conditions being similar.

7. Frost occurs at high elevations only.

We will trace the progress of the radiation and then consider the observed facts above enumerated.

In dry hot weather, as soon as the sun is below the horizon, earth, vegetation, and atmosphere immediately begin to radiate into space the heat which they have received during the day, not all with equal energy, nor are all equally *free* to radiate, were their energies equal, but all in some measure. The vegetation, or say the coffee trees—as it is these we are now considering—are the best radiators, and before long the external parts (for it is only the external parts open to the sky that are free to radiate, the upper primaries, forming a screen to the lower ones) become colder than the surrounding atmosphere owing to their greater radiative energy.

The air, already partly chilled by its own radiation, is further chilled by contact with the colder leaves, and sinks by gravity to the surface of the ground, being heavier than the surrounding atmosphere. This displaced cold air is replaced by warmer air, which, in its turn, is chilled by contact with the leaves, and sinks as before, to be again replaced by warmer air; and so the process continues until a stratum of chill air rises above and envelopes the trees, as it were in a cold aërial bath.

If this were all, however, we should know nothing of frost-bitten coffee, for the air so chilled would only sink to the temperature which corresponds with the radiative energy of the trees, and this temperature is far above the point at which frost is formed. A series of actions and re-actions between the chilled air and the tree now however commences, and it is this that eventually reduces the temperature to the frost point.

It was found by Melloni that, whatever the temperatures of the radiator (in this case the coffee tree) and its surrounding atmosphere, there is always a thermometric *difference* between them remaining pretty constant over a long range of temperatures. In the case we are considering this difference amounts to about 7° Fah. (the tree being the colder of the two), and there is a constant tendency on the part of both tree and atmosphere, to maintain this difference. If the tree be 43° the atmosphere will be about 50°; if the tree be 33,° the atmosphere will be about 40°, and so on.

When, therefore, the tree by its greater radiative energy has chilled itself 7° below the surrounding air, and then by contact has chilled the air to a point below that which corresponds with its own radiative energy, the tree seeks to re-establish the difference of 7° which previously existed, and in so doing sinks lower.

The air is then further chilled by contact with the tree and sinks in its turn. The tree again endeavours to maintain the constant difference of 7°. It is again followed by the air, and so by a series of actions and re-actions the entire stratum of air and the tree itself become lowered to a temperature far below that which is due to their own radiation, and the result is frost-bitten coffee.

Having now traced the progress of the chilling, let us see how it explains the observed facts before enumerated.

Frost occurs only on bright clear nights when the sky is free from clouds, because this is a condition essential to active radiation. Dr. Wells once observed a thermometer placed upon the grass rise 10° Fah. when it came under the shadow of a passing cloud.

Frost occurs only during dry weather, because at other times the aqueous vapour acts as a screen and prevents radiation. "On a day of average humidity in England the atmospheric vapour exerts 100 times the action of the air itself in checking radiation." "The aqueous vapour wraps the earth like a warm garment and protects its surface from the deadly chill which it would otherwise sustain." (Tyndall).

The absence of wind is essential to the proper chilling of the atmosphere, for, if the air chilled by radiation were constantly replaced by warmer air, the action and re-action already alluded to could not proceed.

A little consideration will show why frost occurs on flats and hollows, and not on hill-sides. On a flat the chilled air sinks to the surface of the ground and there remains. When the accumulations have formed a stratum of about 8 feet in thickness, sufficient to envelop the tree, the action and re-action between the tree and the air commence in the manner already described. On a hill-side, on the contrary, the chilled air does not remain on the surface where it immediately falls, but glides gradually down the slope and finally rests at the bottom, or in the hollow to which it naturally gravitates, there tending to swell and hasten the formation of the cold stratum already accumulating in those situations. The chilling on hill-sides does not therefore proceed to a point sufficiently low to form frost. We do not know if the fact has been observed, but we should think it probable that coffee in hollows is some times frost-bitten, while coffee on adjacent flats at the same elevation escapes, the chilling of the former being aided by the flow of cold air from the hill-sides. The descent of the cold air falling on the surface of the slope corresponds so closely with the flow of water falling on the same surface, that the circumstance of frost and damp being found together finds an additional explanation in the analogy.

Frost is apparently formed near dawn, because, the process of chilling being a gradual one, it is towards dawn that the coldest point is reached.

High-topped coffee is less liable to be frost-bitten than low-topped, because it takes a longer time to envelop the high trees in a stratum of cold air. If the chilling were continued, of course the high-topped coffee would eventually become chilled to the frost point.

At first sight it might appear that the lower primaries of both low and high trees would sometimes be frost-bitten while the higher primaries would escape, but it must be borne in mind that effective radiation can only take place from those portions of the tree quite open to the sky, and that the lower primaries are screened by the upper ones. We have, therefore, as regards the lower primaries, early envelopment in a cold aërial bath, but very little self-radiation; as regards the upper ones, late envelopment in a cold aërial bath but active self-radiation. In the result all parts become chilled to the frost point about the same, though it is quite possible to conceive circumstances, and in point of fact they do sometimes occur, under which parts of a tree may become frost-bitten and not others. The "conducting" power of the tree is so small that it hardly forms a factor in the question.

As we write, a report from a well-known visiting agent has come before us, and in it occurs a very instructive remark in the above connection:—

"There has been another visitation of frost which has settled on the same trees that were attacked last year. It is curious how the frost has not injured the sucker which was left to grow, but has blackened the top primary of the original tree."

Now it is easy to see how this has occurred.

Both the sucker and the top primary of the original tree, were free to radiate their own heat into space, neither being screened by the other. The top primary of the original tree, however, came under the influence of a cold stratum of air when it accumulated to the height of two feet or less. The chilling was not sufficiently prolonged to envelop the sucker in a cold aërial bath, and there was consequently only the one cause at work in its case as against the two in the case of the primaries. If, of two trees, side by side, one was cut down to half the height of the other, it will probably be found that, provided the chilling was not too long continued, the low tree would be frost-bitten, while the high one would escape.

It is only at high elevations that frost is formed, because it is only at these elevations that all the conditions are fulfilled which allow of the lowering of the temperature.

As a rule, the air is more humid at low elevations and acts as a screen to intercept radiation. At high elevations too the air is more attenuated and more easily chilled while it has less heat to radiate into space. The range of temperature is greater at low elevations, and radiation must, therefore, be longer continued to produce the same effect. All these causes combined tend to check radiation and maintain the temperature. If two nights could be rolled into one, radiation would be sufficiently prolonged to bring under the influence of frost estates at much lower elevations than those now subject to its attack. Bearing in mind that frost is an uncommon occurrence even at high elevations, it is easy to conceive that it will never occur under conditions even only a little favourable to its development.

Remedies.—Covering the trees with a matting or screen of any sort would effectually prevent radiation: even a screen of cobwebs would have a perceptible effect (Tyndall). Sprinkling the trees with a thin covering of mana grass appears to be the most practicable way of giving effect to this remedy.

Kindling fires when frost is anticipated and on the spots subject to its attacks, would tend to prevent it, not so much on account of the heat imparted to the atmosphere as because a movement of the air would be produced, preventing the formation of a chilled stratum.

The smoke also would interpose a screen between the trees and the sky and check radiation.

Topping the trees high seems advisable even though it lead to the loss of the lower primaries. There is nothing to prevent high trees being frost-bitten if the period during which chilling proceeds is sufficiently prolonged, but practically this will rarely be the case, except with trees in hollows, which require to be topped even higher than those on flats. Where trees have been already topped, a sucker should be allowed to grow up to be topped at 4, 5, or even 6 feet.

J. M. ROBERTSON & Co.

Colombo, 1880.

CINCHONA.

IT seems that although the Government manufactory at Mongpoo turns out 200lbs. of cinchona febrifuge a week, the supply is not quite equal to the demand. We hear that Mr. Gammie's improved febrifuge has been most favorably reported on by more than one medical officer. The improved febrifuge is almost equal to Howard's quinine in appearance.

A NEW Santa Fé cinchona plants, from the supply grown at the Royal Gardens at Kew, are being sent to India by the Secretary of State, to be tried at the cinchona plantations at Ootacamund. These plants were originally introduced from South America. To avoid risk in transit the Secretary of State arranged to send the plants under the care of Mr. Cross who, it was decided, should leave Southampton on 1st September. Mr. Cross will go to Ootacamund *via* Bombay. His passage to India and back will be paid by the Government of India.

A MADRAS correspondent writes :—You will, no doubt, be glad to learn that a trial consignment of Nilgiri cinchona bark is going to Australia, with a view to test the market for this article in the Southern continent. Messrs. Dymes & Co. have obtained 50 bales of bark from the Government Plantations by purchase. The bark will contain a fair proportion of trunk branch and twig bark. It is also to be partly original bark, partly mossed, and partly renewed. Messrs. Dymes & Co. will pay the average price realized at the latest sales of similar bark in England. In making this concession, the Government are anxious to avoid creating a precedent, and state that they are not prepared to depart from the general principle of open competition in the sale of Government cinchona bark.

IN regard to stripping cinchona and mossing in Bogawantalawa (Ceylon), a planter writes :—"I have been mossing my trees here after stripping, but am not at all satisfied with the result. 'I have taken from large trees three strips and from small ones two strips of bark, and have used moss and grass, not mana—the latter by its coarseness and sharp edges injures the cambium if not *very* carefully put on. I find very little difference between moss and grass in the results, though I think the moss, absorbing the moisture from rain better than grass, and not having a tendency to rot, keeps the wound cleaner, and therefore *in a measure* obviates the chance of decay, or possibly fermentation (?), of the cambium setting in." Let our correspondent try the experiment of leaving some of the strips bare, and report the result, but the trees ought not to be too young.

MR. D. MORRIS, the Director of Public Gardens and Plantations in Jamaica, has drawn up a report upon the sale of the fourth consignment of cinchona, which appears in a recent *Jamacia Government Gazette*. He remarks :—"The most encouraging feature in the present sales is the fact that all the bark despatched in April was 'sun-dried' bark. Considerable discussion has taken place during the last six years in India, Java, and Ceylon, with regard to the proper method of drying cinchona bark. Some maintain that under exposure to strong sunlight the bark deteriorates and loses some of its valuable alkaloids. On the other hand the advocates of 'sun drying' affirm that, in order to preserve the chemical components of the bark intact, it should be dried as rapidly as possible before any internal fermentation takes place. As cinchona bark could not be dried here artificially except at a considerable cost, it was most necessary to test its value, when dried by full exposure to the sun. The result, as shown by the present sales, is most conclusive. In competition with artificially dried and other barks, it is satisfactory to find that Jamaica 'sun-dried' bark obtained the highest prices. It may therefore be safely assumed that cinchona bark cannot be dried too quickly or too thoroughly. To this might be added that it should be packed perfectly dry, and despatched with as little delay as possible."

MR. GAMMIE ON CINCHONA CULTIVATION.

WE publish elsewhere a letter from Mr. Gammie, on the above subject, to the *Ceylon Observer*. The following comments on this letter are extracted from an article in the Colombo paper :—

The splendid success which has attended Captain Cox's *Ledgeriana* enterprise shews what can be done in Ceylon, under similar conditions, and his remarks about hybrids should afford consolation to gentlemen who, discouraged that they have not the "Simon pure" in *Ledgeriana*, may yet find in a vigorous growth, some compensation for a lower percentage of valuable alkaloids. From this point of view, we call attention to the letter of Mr. Gammie who, in Northern India, is rapidly securing for himself the prominent place which the late Mr. McIvor held among the cultivators of cinchona. If Mr. Gammie's discovery of a cheap and ready mode of extracting sulphate of quinine, even from some of the less valuable barks, stands the test of being applied on a considerable scale, his name will be associated with an immense forward step in the history of the Indian Government enterprise. * * * * * * * * His surmise, that the powdered bark from Java which proved a commercial failure was of inferior quality, is correct. Mr. Moens told us that in further experiments he had got as good a price for powder and shavings as for quill. In respect of bark for manufacturing purposes it is, we suppose, once for all settled now, that whether in powder, shavings, pieces, or quills, the mode of packing is quite immaterial. The product is valued and bought by analysis according to its inherent quality, and with little or no reference to outward appearance. Both in respect of the "scraping" and "grafting" processes, Mr. Gammie's experience stands in contrast to that of Mr. Moens, who is thoroughly well satisfied with the result of his grafting of *Ledgeriana* on to *succirubra* stocks. In reference to Mr. Gammie's remark about the Sikkim *Ledgeriana* reproducing itself truly by seed, Mr. Moens has called our attention to a paragraph in a report he wrote in March 1877, as follows :—

"In British India the propagation of *calisaya* by seed is not ventured upon for fear of degeneration. This is almost tautamount to abandoning the cultivation of it for the Calisaya generally. With *Ledgeriana*, specially, the propagation is so difficult, and so many cuttings afterwards die, that the prospect is not encouraging. I believe the fear to be exaggerated. It is true that among seedlings for the self-same tree, there are always found a few differing in form or in colour of leaf, though the greater part closely resemble the parent. But this is also the fate of other species of *officinalis*, and, in a lesser degree, of *succirubra*. And now experience has taught that both *officinalis* and *succirubra* are richer than before, instead of poorer, in alkaloids than the American parent plants Again, our trees of this species are seedlings of British Indian plants, and it is already above all doubt that the bark obtained here is certainly not poorer in alkaloids than that of the stock of plants in Ceylon and Madras The plants which have been cultivatd from the original American seed of Ledger differ also very much among themselves in form and even in colour of leaf, and in form of fruit and flower—and yet they are all very rich in quinine. I have many grounds for thinking, and hope also to be able to prove it in a couple of years, that the fixed yield of a plantation, raised from seedlings of cinchona *Ledgeriana*, shall agree with the yield of the parent plants, and that in such a plantation not only shall be found trees which are poorer, but even many which are richer in quinine than the original plant. As for fearing the decay or the deprivation of the whole there really exists no reason for it."

Our planters, therefore, who have received *Ledgeriana* seed direct from Mr. Gammie, as well as from Mr. Moens, should have little fear of the result; for bark yielding 7 per cent. of crystallized quinine at four and five years old may well be accepted as true *Ledgeriana*. In reference to the Carthagena bark, Mr. Moens' experience is not favourable. He says the rapid growth is all that Mr. Gammie describes, but the result by analysis, at least in Java, was unsatisfactory. The more reason therefore why our planters should follow our correspondent's example in not despising their old friend *succirubra*. Mr. Gammie's prophecy that 'common' red bark will yet be *the* species to yield a cheap and efficient ferbrifuge requires to be carefully noted, for he himself may yet be the agent through whom the prophecy will be fulfilled. We refer to the experiments he is now conducting in which we and the Ceylon planters may well hope he wil have a full measure of success.

MR. JOHN HOWARD ON CINCHONAS.

THE following is a copy of a paper on cinchonas contributed by Mr. Howard to a recent number of the *Gardeners Chronicle* :—

In a previous communication (last May) I dwelt upon the success of the cultivation of cinchona in Java, reserving what I had to say respecting the British plantations. I am now able to speak with certainty as to the yield of these latter for the year 1879, having before me a table compiled with great care by Messrs. Woodhouse, Mincing-lane, for private circulation, giving all particulars of the importations from every estate in India and in Jamaica. The total number of packages from the Government plantations at Ootacamund amounts to the following :—From Dodabetta, 429; from Nediwuttum, 779; from Pykara, 241. From Jamaica 16 bags are next recorded. From private plantations on the Neilgherries, 577; from Darjeeling, 1,050, and from Ceylon, 6,229.

The compilers say :—"In handing you the accompanying tables, we think it well to call the attention of planters to the following features :—In the first place, the extreme rates realised by the renewed bark, both crown and *succirubra*; the prices, as compared with the natural bark, being in most cases nearly double, and in red bark frequently more. This is to a great extent accounted for by the analysis. * * The highest price paid during the year was 12*s*. 8*d*. per pound for eleven cases renewed crown marked W. R. A. } Prospect. } The largest private estate appears to be in Darjeeling, which sent out 944 packages. . . These realised full prices, the long selected quills being especially suitable for druggists. The chief feature in Ceylon descriptions is the very large proportion of twigs and shavings amounting to 3,089 packages out of a total 6,229."

The prices obtained for the bark from Ootacamund ruled much higher than those obtained for the Darjeeling lots, none of which fetched more than 2*s*. 10*d*., but some of the Ceylon bark brought from 7*s*. to 8*s*. We may safely conclude that the introduction of the red bark (*C. succirubra*) has been quite a success, especially when the bark can be renewed according to the process of the late Mr. McIvor. The tree retains its peculiar properties as to chemical constitution under all circumstances.

The true *C. officinalis* var. *Uritusinga* has also prospered well at the Dodabetta plantation. A large portion of these trees, represented in my *Quinology of the East India Plantations*, are also producing excellent bark. They had attained an average height of 28 feet, with a girth of 22 inches in 1878, or fifteen years' growth (*Ceylon Observer*, January 16, 1879) having been planted in 1863; and, according to the Government report, yielded 38,801 lbs. of bark in the year 1877-78. The prices obtained were—for the natural bark 7*s*. 1*d*., mossed bark 9*s*. 8*d*., and renewed crown 10*s*. 11*d*.

A considerable number of these trees were the descendants of a plant, about 5 feet in height, which I presented to the Indian Government, having received the seed from the mountains of *Uritusinga*, near Loja, in South America. This small tree arrived in April 18, 1862, at Ootacamund, in a languishing condition, but thanks to the skill and care of Mr. McIvor, it began to recover; so that by May 31, it was possible to obtain some cuttings, and by December 31, 1863, this one plant had produced 6,850 new ones. At a subsequent period Mr. McIvor told me these had multiplied to more than 60,000, so that a considerable portion of the Dodabetta plantation must consist of its descendants. The bark of these tree

given me by Mr. McIvor yielded 7·40 per cent. of fine sulphate of quinine. I have, therefore, recommended those who wish to plant crown bark, to obtain seed from this Dodabetta plantation. The habit of the plant may be seen from the accompanying woodcut (fig. 73) of one of the plants which I obtained from its native habitat, and have described in the *Nueva Quinologia*. According to its discoverer, Pavon, it grows to the height of 60 feet and more.

The narrow-leaved form which re-appeared in India, and produced nearly 10 per cent. of quinine, appears to have been considered by Pavon to be identical with this; so in my Pavon MS. it is written *olim angustifolia*. The *Urittusinga* is described finally as *foliis lanceolatis*, and "*angustis* is (rightly) erased. I have seen the leaves vary on the same plant. The other variety (fig. 74), photographed from a plant in my conservatories, of the var. Amarilla del Rey, now called Bouplandiana, does not rise beyond the dignity of a tall shrub. I cut down the leading stem, and this yielded, on analysis, quinine and cinchonidine in nearly equal proportions, also cinchonine. It is therefore a variety less adapted for cultivation—at least when the soil is rich, though it may be suited (as in Ceylon) for some exposed situations with shallow depth of earth. I have figured it in plate XI. of my *Quinology of the East Indian Plantations*

It is very difficult to say what are the predominant species in cultivation in addition to those above-named, especially as we have no satisfactory report of the amount of hybridization that may have occurred. All the *Calisayas* introduced by Mr. Markham perished owing to the salt water having penetrated to the roots of the plants in passing down the Red Sea, and a like fate, though not from the same cause, befell most of the *Ledgerianas* raised from seed at Ootacamund. The climate may be too severe as the neighbourhood is described (in the *Ceylon Observer*) as in the language of one of our northern countrymen the very "trysting place of the winds." The Pitayo barks have been introduced, and it is very desirable that their cultivation should be extended. I do not think that the true *C. officinalis* ever existed at Darjeeling or in Ceylon. The attempt to grow crown bark at the former place has been (as I understand) a failure; from the latter I have specimens of the *angustifolia* form, but not of the *C. Uritusinga*. *C. Calisaya* from Darjeeling, (as far as specimens have fallen under my notice), is very poor in quinine.

It is to be regretted that since Mr. McIvor's death and the (not so very mysterious) disappearance of Mr. Broughton, there has been so little scientific guidance afforded to the cultivators. We are indebted still to Java for this.

Whilst I am writing there comes to hand the following comparative analyses obligingly sent me by the Dutch authorities from the same tree of *C. Ledgeriana* :—

Bark dried in sunshine.

Quinine	11·66
Cinchonine	0·32
Amorph. alk.	0·45
Total	12·43

Bark dried by artificial heat.

Quinine	11·68
Cinchonine	0·31
Amorph. alk.	0·51
Total	12·50

I have under my eye a botanical specimen, sent by a planter in Ceylon, with bark for analysis. He says that it is pronounced by Dr. Thwaites "pure *Calisaya*, with which definition I quite agree, but the flowers are said to be white, which shows variety (in so far) from the a vera of Weddell. They are quite unlike those of the variety *Ledgeriana*. The bark gives a produce equal to 3·4 per cent. of sulphate of quinine. I think that this may be the same as the Darjeeling sort existing under more favourable circumstances in Ceylon.

It appears from Dr. King's issued report on the Government plantations in Sikkim (*Ceylon Observer*, February 4, 1880), that the number of trees there planted out amount to more than 4,000,000. In Ceylon and other parts of India the cultivation is also being carried on with great vigour. Some of the planters are becoming alive to the necessity of care in selecting the best species, and the measure of success already attained with the *Ledgeriana* in at least one quarter, encourages the best hopes.

We find in the report of the Commissioner of Neilgherries (no successor to Mr. McIvor having been yet appointed) much interesting information (*Ceylon Ob server*, December 18, 1879.) Under the head "nurseries" Mr. Barlow states that "604,855 plants, were distributed to the public during the year, ag ainst 187,850 in the previous year. [The question arises, of what kind, or form, or species were these.] The quantity of seed distributed was 1,822lbs. against 826lbs. in 1877-78. Most of this seed was sent to Ceylon where I believe it is sown broadcast amongst old coffee."

The editor of the paper from which I quote, remarks further :—"We have seen it stated that 80,000 seedlings is a fair average number to be expected from 1lb. of cinchona seed; although a planter at Kandapoola tells us he has got 250,000 from 1lb. of *C. officinalis* seed from an estate in Dimbula. Practically, he reports every seed grows. . . . . . To return to the enormous quantity, 1,648lbs, distributed from the Neilgherry plantations, in India and Ceylon, in two years! At the moderate average of 80,000 seedlings to lb., the result would be no fewer than 131,84 ,000 plants from this source, apart from seedlings from private plantations in India and Ceylon. This would probably raise the total to 200,000,000 of seedlings—about enough, one would think, to stock the whole of the hill countries of India and Ceylon."

Your readers will bear in mind that this is all theory, except, indeed, the fact that every seed placed in favourable circumstances may be expected to germinate. Fortunately for the planters themselves, no such calculation as the above holds good in reality. The world is in no danger for some time to come of being inundated with bark from India. The whole supply from all quarters probably would not suffice to keep the quinine manufactories at present existing in full operation.

But another factor in the calculation has to be taken into account—that in more than one quarter (as I have reason to believe) highly successful efforts are being made to cultivate the best sorts in their native climes in South America.

I will not add to the length of this paper by furnishing deductions which your readers can supply for themselves. I have sought to present facts as far as space would permit for the formation of a judgment on the whole subject.—*John Eliot Howard, F.R.S.*

SERICULTURE.

THE recent attempt to re-introduce the silk industry into the Kangra Valley is meeting with considerable success.

We take the following from a Japan paper, the *Nichi Nichi Shinbun* :—"The silk crop in Italy is very bad this year, and only amounts to one-third of the usual year's outturn, so that she must seek her supply from other countries. The foreign silkworm merchants who lately arrived here, gave orders for the purchase of large quantities of silk, but they offered as low prices as before. The amount of silk manufactured in the province of Shinshiu is so small that it will not suffice even for home consumption. On receipt of the news of the bad crop in Italy, the native manufacturers raised their prices, and foreigners having now experienced these unexpected difficulties, intend making different arrangements this year. On the other hand, the native silk manufacturers fearing that when the goods are sent to Yokohama, very low prices will be offered, intend sending them up to Tokio. A report from Yokohama says that about nineteen Italian silkworm merchants arrived here on the 18th instant."

TASAR SILK PRODUCTION AT LAHORE.

IN our last issue we gave an extract from "Mr. Morgan's account of his attempt to domesticate Tasar silkworms in the Madras Presidency. We now give the following account, taken from the local print, of the operations that are being conducted at Lahore :—It may interest some of our readers to know that Tasar silkworms are now being reared in the gardens of the Agri-Horticultural Society at Lahore. Mr. Spooner, the Superintendent, has a number of cocoons from which the very handsome Tasar moths (called now *Anthœrea Siwalika*) are being daily hatched. The moths are kept in a large cage of split bamboo, and the eggs, as they are laid, are collected and hung on to a *bér* tree in the garden in small leaf baskets. The worms hatch out in nine or ten days after the eggs are laid, and the tiny brown insect, a few lines in length, climbs out of the basket on to the branches of the *bér* and begins to eat voraciously. The quantity of green leaves devoured by these small creatures is extraordinary, and in a few weeks the small brown worm has developed into a large caterpillar, of a bright pea green color, from three to five inches in length, adorned with remarkable spiracles, like small round pieces of looking glass inserted into the sides of the animal. The caterpillar spins its cocoon in 35 to 40 days, and during last month (August) several small *bér* trees in the gardens, on which the previous generation was reared, were covered with cocoons. These cocoons are now developing a second crop of moths, for the worm is bivoltine, that is—the animal goes through all its stages of caterpillar, chrysalis, and perfect insect, twice in the season in the Punjab. The cocoons produce a harvest of moths in July, and the worms developed from the eggs of these moths spin cocoons again in September and October. Thus it is the second crop of the season which is being reared now, and the cocoons which will be all formed by the end of October will hang on the trees throughout winter and spring, till the first rains in June and July, when the moths will again burst forth from their long slumber in the chrysalis or cocoon state. Tasar silk is now so much in demand that the experiment of domesticating the Tasar silkworm is one of much interest. The worm is indigenous in the Punjab, as in many other parts of India, and the facility with which it may be reared on the *bér* tree in the open, without the expense and trouble of daily cutting and collecting leaves for its food, which is entailed in the case of the common silkworm, the *Bombyx mori*, gives hope that the cottage cultivation of the worm in a semi-domesticated state may yet become a remunerative industry in the country. The experiment is well worthy the attention of the intelligent members of the native agricultural community.

TOBACCO.

ALTHOUGH India produces good tobacco, last year she imported 88,082 lbs. of manufactured tobacco, valued at Rs. 2,73,388. Of other sorts she received from foreign countries 621,248 lbs., worth Rs. 3,52,568. The exports of unmanufactured tobacco from this country reached 10,874,623 lbs., and was worth Rs. 11,67,025. Manufactured tobacco was exported to the value of Rs. 97,633, and other sorts to the value of Rs. 33,439.

THERE appears to be no doubt says the *Ceylon Times*, that the soil and climate of the Cottiar, district near Trincomalie, is extremely suitable for the cultivation of tobacco, but to render it independent of the long spells of dry weather which prevail in that part of the island, artificial irrigation will be absolutely necessary, and this involves outlay of capital to carry it on upon a suitable scale. About 3 cwt. of excellent tobacco grown from Sumatra seed has been cut and cured, but not grown by the gentleman who has settled in the district from Sumatra where he was most successful: he has been but a short time in the island, and has not yet essayed the cultivation of the plant. During the rains of November a good extent of land will be planted up with seedlings raised from Sumatra seed. The quality of the cured leaves is said to be unexceptionable, and should the sample about to be consigned home for report and valuation answer the expectations of the growers, the cultivation will be still further extended.

TOBACCO AND SUGARCANE MANURES.

A WRITER in the *Madras Athenæum* has the following:—The excrement of cattle and sheep is not favourably thought of in South America, as a manure for tobacco or sugarcane. It is used however for coffee and other crops. I will give you the opinion of that great chemist Baron Liebig on the best manure for sugarcane.

Baron Liebig gives the following example, he says "I took three acres of the best land I could find, in the first, I planted sugarcane without manure, it produced a good crop. The second acre manured with farm yard manure and city sweepings, well mixed; the product was much more than the first acre. The third acre I manured with "Poudrette," one ton to the acre, the produce of the third acre over the second was some several (the writer has forgotten the exact figures) tons." Does not this then prove that Poudrette, is the best manure for sugarcane? The Japanese use night-soil in preference to any other manure, and say that "Man more than any other animal, consumes more from the earth; and should therefore return to the earth what he took from it."

Below, the writer gives Baron Liebig's receipt for making Poudrette, but will say "He has himself grown splendid crops of sugarcane, manured as follows":—

1 Ton good farm yard manure.
2½ Cwt. night soil.

Mix well, but do not use any lime, as the lime being very caustic would cause all the ammoniacal salts to evaporate from the night soil.

Poudrette.

1 Part night-soil.
1 Part burnt wood or vegetable ashes.
1 Part good common earth.

Mix thoroughly (do not sift it) and let it lie in a shady place for one week, mix once more and apply one ton to the acre.

Any good farm yard manure (sheep dung excepted) will suit for tobacco, but it requires to be well ploughed into the ground, or, if manure be scarce, you can work it in, at every intersection of the row, where you set the plant. Do not be too sparing if your land be poor. Farm yard manure mixed with night-soil will bring splendid crops of tobacco. For top dressing grass lands you can use cattle manure, *viz.*:—

4 Parts cattle manure.
2 do. good earth.
1 do. lime (chunam.)

Mix thoroughly and scatter evenly on the surface before rain, it will sweeten and improve your grass.

TOBACCO CULTIVATION IN VICTORIA.

THE SOIL AND ITS PREPARATION.

A DRY warm soil (loam or sandy loam), rich, deep, and containing lime, is most suitable for tobacco. The more sandy, to a certain degree, the soil is, the better will be the quality of the tobacco. The nearer the soil is to clay, the poorer will be the crop, under similar circumstances, although the yield may yet be satisfactory. Wet and stiff soils are not, under any circumstances, suitable for tobacco. Old or poor land must be well manured; the land must be ploughed deep, ten or twelve inches, and harrowed thoroughly until it is as fine as garden soil.

This is best done by ploughing early in the autumn, exposing the rough and hard furrows to the weather. After the soil is dry, it should be harrowed thoroughly, then ploughed across, and harrowed a second time, and rolled before planting. The different ploughings, &c., should of course, be done at intervals long enough to allow the land to settle and mellow.

This is the treatment of soil which has been cultivated with the plough, before tobacco is grown on it. It is somewhat different with newly-turned (virgin) soil which the tobacco particularly likes. Deep and thorough workin is the rule here also, but it is done in a different way. In the virgin soil all the roots must be picked out, because they would make the soil too loose for the secure insertion of the plant, and then they would hinder the grower with the hoe and plough to a great extent. The land is broken up, about three weeks before planting, 10 to 12 inches deep, taking care that the furrow is entirely turned, so that the grass is placed at the bottom. After from eight to 14 days, when the soil is settled, it is thoroughly harrowed in the direction of the furrows, to prevent the sod being turned up again, which must remain below, undisturbed.

Shortly before planting the soil is harrowed again, and, if necessary rolled; this time it may be done crosswise. This treatment has these advantages—the newly-turned sod prevents the weeds from coming up, and the under-turned grass acts as manure. I must here caution all intending cultivators of tobacco not to attempt to grow it on poor land, without well enriching with animal manure.

In Virginia and the Western States of America, where tobacco cultivation has become a science, they think it is not too much to plough in 40 loads to the acre, their maxim being, the richer the land, the heavier the crop. And on no account plant the same land with tobacco for three consecutive years. Guano, sheep dung, or stable manure are all suitable.

TRANSPLANTING.

As soon as the seedlings are of the size of cabbage plants—that is, having four leaves, and being four to six inches high—they are ready for transplanting. The first thing is to lay out the land in lines with a one-horse plough. These lines are either furrows or ridges—according to whether there is little or much rain expected, or as the soil is more or less porous—the furrows give the young plants shade, and protect the soil from drought by sun or winds; the ridges absorb the sun and protect from dampness. In this respect the planter must be governed by experience. Ridges and furrows may be omitted in small plantations; a strong cord is stretched over the whole width of the field by stakes at each side, and one in the middle; alongside this cord the plants are inserted at regular distances, which are shown by some mark on the cord. When one row is planted, the cord is removed to the next, and the planting done in the same manner, and so on until the field is done. This method has the advantage that the soil may be made fine with the hoe shortly before the inserting of the plant, if it has not been done sufficiently by horse labour. However the rows may be made, they must be equally far apart, and so with the plants in the rows. The distance apart depends somewhat upon the richness of the soil, for very rich soil will grow larger leaves than poor, and then it must be considered whether the after cultivation is to be done entirely by manual labour, or partly by horse power. The farthest distance for Virginia, Kentucky, and Connecticut is with the rows four feet, and the plants three feet in the row; but I think that on most lands in this colony, three feet between the rows, and two-and-a-half between plants, would be the best distances.

When all is ready for transplanting, watch must be kept for rain, or for one or two cloudy days. If the weather is favourable, the planter must lose no time, but go to work with all the hands at his disposal. Notwithstanding the hurry, everything must be done methodically, and in proper order, for all carelessness in transplanting tobacco is severely punished by the necessity for renewing plants which fail. After thoroughly wetting the seed-bed, proceed in the following manner to remove the plants:—Take a common two-pronged dinner fork, or a stick, sharpened to a flat point at one end; run this down by the side of the largest sized plants (which should be always planted first), with the other hand gather the leaves carefully, and gently lift them out of the ground, so that the roots will not be hurt, and the earth not disturbed around the remaining ones, and only take out as many as can be planted in a short time. As soon as taken up they are laid straight in a basket, and the roots covered, and transplanted at once. This is best done by having two persons to plant, one (a boy will do) to drop a plant at the requisite distance, the other to insert them in the soil. This latter is done by taking plants by the leaves, near the roots, in the left hand, and with a dibble, or with the hand, make a hole where the plant is to grow, by running the dibble down straight; withdraw it, and place the roots of the plant, held in the other hand, in the hole, taking care that the roots are not doubled up, and with the aforesaid dibble push the dirt up to the side of the roots, finish off by pressing the dirt in and around the plant. If the weather is favourable, this must be continued until all is completed, but if there is no rain, nor cloudy days, and trasplanting cannot be postponed any longer, the grower must water the plants at time of transplanting, and cover them immediately after; this requires the additional help of three persons, namely, one who waters, one that puts dry earth around the watered plants so that no lumps will form there, and a third to shade the plants. Transplanting, under these circumstances, can only be done mornings and evenings, and should even be done *only* towards evening. Shading is done with leafy branches, straw, bark, or shingles. After the transplanting, care must always be taken that the plants, until they are rooted, are not suffering from want of moisture, and it may be necessary that they be watered a second time. Dead or weak plants must be removed, and replaced by healthy ones.

In some of the tobacco-growing districts of the United States, the young plants are attacked immediately after transplanting by a large brown or black worm, called the cut worm, and though I have not seen them in this colony, it would perhaps be as well to keep a look-out for them;

you can tell where they have been by seeing a plant with the leaves eaten off and drawn down into holes about the roots, like small ant hills. By poking about a little in the dirt you will find the worm very near the mouth of these little holes. This fellow is quite distinct from what is called the tobacco worm.

WORK UNTIL HARVESTING.

This work is done partly for the benefit of the soil, and for that of the plants themselves. The working of the soil is for keeping it open to the influence of the atmosphere, and to destroy the weeds; experience has proved that only soil that is open and free from weeds will fully develop the plants. Loosening and stirring the soil from time to time is, therefore, not only beneficial but necessary, especially when the soil is hardened by heavy rains, or a crust has formed through other influences, when weeds appear. It is important that the soil should be kept open with the plough, scarifier, or with hand-hoe.

In the rows between the plants, where the working is even more important, it must be done with the hand-hoe. Care must always be taken not to damage the roots, and at the second, and especially the third hoeing, the soil must be drawn towards the plants partly to protect them against storms, and give them a stronger hold, and partly to absorb excessive moisture.

The soil must never be worked while wet. Where help is plenty, it is better to dispense with all horse work, the plants can be put closer together, a larger crop is gained, less damage is done to the plants, and, in closing up the accounts, the cultivator with manual labour will not be the loser.

WORMS.

The tobacco having got up to 10 or 12 inches high look out for the green worm which eats the leaves; they are often found earlier. You will see a small round hole, oftentimes no larger than a pin-hole, in the leaf; if you turn it up you will be very apt to discover on the under side a small worm of the diameter of common thread-needle, and half an inch in length; kill him and all his kind, for if left, he will grow to the size and length of your finger, and would not make much of a breakfast of a third of a full-grown leaf. These worms are hatched from eggs deposited by what is called the tobacco fly—it is a large dusky brown-winged miller. The eggs will hatch out in 24 hours. Look out and destroy these eggs; they will generally be found on the underside of the leaf, and near the edge. Much of the value of the crop depends on the care and attention in performing this part of the work, the plantation therefore, should be gone over carefully at least twice a week.

A flock of turkeys, if given access to the tobacco-field, is a very valuable help. A negro from South Carolina told me, some time ago, that a solution of blue vitriol in water, sprinkled over the plants, will kill the worms. The remedy may be worth trying—of course, the solution must be made weak enough so that it will not destroy the plants as well as the worms.—*Australasian.*

NOTICES TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

CORRESPONDENCE.

THE CENTRAL PROVINCES TENANCY BILL.

TO THE EDITOR.

SIR,—In your issue of November 1, 1880, you have noticed the attitude taken by me with regard to some provisions in the Central Provinces Tenancy Bill; and you regret that I should have pleaded the cause of the landlords.

It is far from my desire to assist either party to the unjust detriment of the other. Experience has shown me that if the law interferes at all it must make its work complete and effectual. To give a tenant an occupancy right without fixing his rent, is like giving a man a property which is in chancery. The landlord will use the law to enhance the rent, and he will win in the long run. No cultivator can stand the expense and loss of time caused by constant litigation.

This was proved by one experience of Act X. 1859, in the North-West. When the rent law of the N.-W. P. was revised in 1873 I endeavoured in concert with Mr. C. A. Elliott and others to get a provision inserted fixing the rents of all occupancy tenants for the term of settlement. A measure of that kind would have placed some seventy per cent or more of the cultivators in comparative security. The dense population of the North-West, the keen competition for land, and the pitch to which rents had already been raised, justified, I think, if they did not necessitate this measure.

The advocates of this proposal were not strong enough to carry it against the high authorities who opposed it. A compromise was effected which prevented the tenant's rent from being enhanced more than once in ten years, except under certain conditions.

I have not changed my views on this matter since 1873. But the proposal in the Central Provinces Bill, while giving the five-year tenant the embryo as it were of an occupancy right, leaves him open to suits for enhancement of rent every year. In other words it enables the landlord who is so disposed to ruin him; according to law, it is true, but to ruin him all the same. At the same time it makes him an object of hatred to the landlord. He is the beginning of a more independent being, the twelve-year occupancy tenant, who will be open to little enhancement. He is like a pawn who is being pushed down to the end of the board. In a few moves more it will become a queen.

The Bill certainly meets one of the great evils of the twelve-year rule, by only requiring residence in the village, cultivation of some, not the same land, and independence of the landlord's assistance. The five-year occupancy cannot be stopped by making a tenant change his land. But it can be stopped by making him give up his land altogether for a year, and no doubt there are landlords who will do this. It can also be stopped by forcing the tenant to take "assistance"— whatever that may mean. Before he comes to his fifth year, he is at his landlord's mercy. He will be told in his fourth year to take "assistance" or go. For the "assisted" the law has no protection. Another important consideration is this. Heretofore in these provinces the landlords or malguzars, as they are here styled, have very generally supplied their tenants with seed, and also with food in time of need. They take very much the same interest for advances as the money-lenders task. If the advance of seed or food grain at the usual rate of interest is to be called 'assistance,' then this provision of the Bill will have little effect but to excite a mass of litigation. The tenants will claim protection, and the malguzars will win by proving "assistance."

On the other hand if a malguzar who assists his tenants is to gain nothing, in bad seasons these tenants, who cannot stand by themselves will suffer or come upon the State for support.

Even putting out of consideration the facilities which the bill leaves to the landlord for contracting himself out of these provisions, the sections appear to me to breed strife without any corresponding benefit.

Then it must be remembered that some consideration is due to the landlord's view. But a few years ago we took him, only a farmer or thikadar, and made him into a proprietor of land with much sound of trumpet and loud songs of triumph. There is room for thinking that the transformation was a mistake. But has he grossly abused the power we gave him? Do the safety of the State and the needs of justice demand, as they loudly call elsewhere, that his powers should be withdrawn? I think not. In fact land is too plentiful and men too few in the Central Provinces, to give him the opportunity of oppression. The provisions of the Bill savour of an attempt to destroy as much of the settlement with proprietors as it is possible. It would perhaps have been a good thing to make a ryotwar settlement. If it is shown to be a good and necessary thing to revert to that system, I am prepared to support it, on just terms to the landlords. But I do not think it can be said that the present arrangement in the Central Provinces has proved a failure. Are we then justified in passing measures which, if they are to be effectual, must necessarily encroach on the rights and profits which the proprietors as created by our own Government have hitherto enjoyed?

The circumstances of the Central Provinces differ materially from those of the crowded parts of the North-West and Lower Bengal. Malguzars still have to take care of their tenants, and endeavour to get their land brought under cultivation. In order to prevent oppressive practices from growing along with the increase of cultivation, some measures may be needed. Perhaps if an exacting and tyrannical malguzar were made liable to suspension or removal by the Executive Government it might be possible to maintain an efficient check over the avaricious and unscrupulous. It may be doubted whether any good will arise from the fanciful and half-hearted proposals of the Bill.

I remain, yours faithfully,

C. H. T. CROSTHWAITE.

ABOUT PAPER FIBRES.

TO THE EDITOR.

SIR,—In my last letter I proposed to point out some few of the fibres enumerated in Mr. Liotard's Memorandum (Indian Blue-book) which offered a reasonable prospect of success to supplement the supply of paper-making material for our English requirements.

After carefully reading and considering the very voluminous lists of fibres and fibrous products furnished by the various authorities in Mr. Liotard's compilation, I fear there is but faint prospect that any single one of the fibres therein referred to can be imported into England *in its purely raw or natural condition*; and this simply from the fact of the heavy cost for freight alone from any port in India to Europe to say nothing of cost of transport from the locality of production to the port of shipment.

All raw fibres in their natural condition as grown or produced are extremely bulky, and from my present experience I do not believe that any raw fibre can practically speaking be compressed into less bulk than 60 cubic feet, say 1½ ton measurement, and this for freight alone.

Many years ago I erected the first hydraulic presses in Spain for baling *Esparto*, and I then thought I did well in compressing the grass into from 70 to 80 cubic feet to the ton; lately, by employing the costly compound hydraulic presses similar to those used for cotton and jute in India, *Esparto* grass has been compressed into nearly 50 cubic feet per ton.

Assuming such presses to be adopted for any *purely raw fibre* from India, we have still to face the outlay for *freight alone* of from £4-10 to £6 per ton, leaving no margin for cost of collection, internal carriage drying, baling, and other charges to say nothing of profit—I mean little or no margin, unless such raw fibre should be much superior in quality to *Esparto* grass, or Alfa, which now rules the market, the lower grades indeed I may say the greater portion, selling at from £5 to £7 per ton; thus it will be obvious that it is extremely difficult to indicate *any purely raw fibre* that can comply or compete with these onerous conditions.

That there are abundant raw fibres that will meet Indian requirements I doubt not, but so far as supplying the English market is concerned, to ensure commercial success, my conviction is that *any raw fibre* must be subjected to some preliminary process of preparation or treatment to reduce it into a carrying or economically transportable condition.

The only fibrous product from India that as yet has come into the English market, available as a paper-making material, is jute:—known as "jute butts or jute ends," these being the waste ends nearly fiberised, but with fragments of the bark, attached, resulting from the preparation of the long cleaned jute of commerce. I have bought jute butts at £8-10 per ton, but they at present command from £10 to £12 per ton, and being as it were, a waste or by-product, and reduced by compound hydraulic pressing to nearly even weight, secure the minimum of freight, and thus no doubt leave a fair margin of profit to the exporters. These butts are used for a variety of coarse textile purposes, and enter very largely into the manufacture of paper, both in this country and the United States, but, being costly and difficult to bleach, are but sparingly employed for white papers.

Now it is well known in India that long clean jute sells in the market from £16 to £24 per ton, but there are many fibres referred to in Mr. Liotard's Memorandum, which, as long clean fibre fit for spinning purposes, fetch far higher prices than jute, such as Manilla and Sunn hemps aloe, fibre, &c., &c., ranging from £25 to £40 per ton. The tow waste resulting in the preparation of these fibres, if clean and of fair quality would, if available in quantity, fetch a higher price than "jute butts," being superior paper-making materials.

At page 3 of Mr. Liotard's book, reference is made to the crushing rolls I sent out to India for crushing bamboo, and it is suggested that the same, or a machine of reduced size could be applied for crushing plantain stems. No doubt these or indeed any rolls would crush plantain stems, but, unlike the bamboo, the plantain stems would have to be submitted to some subsequent treatment to free the true fibre from the mucilaginous and pulpy mass in which it is embedded. The same treatment would be required for aloe leaves, and other *endogenous* plants of a similar character, and so far as I know the apparatus has not as yet been invented that will perform this operation —to produce the fibre at a sufficiently low cost and sufficiently clean to come into the market as paper-making material. In point of fact all the Manilla hemp, aloe, pita pine apple, and similar fibres have hitherto been produced or prepared entirely by hand labor.

For the *exogenous* fibres, that is, those derived from the *liber* or inner bark existing outside a reedy or woody interior stem, some mechanical arrangements have been adopted to supplement or assist purely hand labor; but these have been confined to the production of long clean fibre suited for textile purposes, the tow waste *only* being available for paper material. To treat such plants purely for paper-making material much more simple mechanical and other means with less labor must be employed to produce the fibre within remunerative limits as to cost.

In most plants the really available fibre represents but a small portion of the bulk of the plant, and, somewhat similar to the gold existing in the quartz veins of India, requires mechanical and other appliances to disunite it from combined extraneous matter, as the pure metal gold is separated from its component matrix.

With the exception of the grasses, reeds, or sedges, very few fibrous plants, either *endogens* or *exogens*, yield more than from 9 to 15 per cent (of pure fibre. For example, neither the plantain stem nor the aloe leaf (both *endogens*—inside fibre producers) will yield more than from 9 to 12 per cent pure fibre, while hemp and flax, illustrating *exogens* (outside fibre growers), yield only from 12 to 15 per cent. In other words it requires on an average 7 tons flax straw to produce 1 ton flax fibre.

It will be obvious, therefore, that—putting on one side the yield to the acre if cultivated, or, if a wild plant, the cost of collection—considerable expenditure must be incurred even to reduce any *raw fibrous plant* into a condition to enable it to be transported economically to Europe from India, whether it be for textile purposes or paper-making. And equally clear is it that, as the selling price of such prepared fibre for paper-making material must be low in order to compete favorably with the existing materials employed, such cost of preparation, with freight and carriage added, must not exceed the value the said fibre will realise in the market.

The question therefore is while describing such fibrous plants as will yield *paper-making material* to point out those from which resulting fibre can be prepared at a cost likely to command commercial success, that is, to pay both the producer and importer,

THOS. ROUTLEDGE.

Claxheugh, 27th October 1880.

THE *SORGHUM SACCHARATUM*.

TO THE EDITOR.

SIR,—I am anxious from the description given of "A New Cereal" in your July issue of the *Indian Agriculturist*, to make a trial of it here. I should feel greatly obliged if you will kindly tell me where and to whom to apply for a small quantity of *Sorghum Saccharatum* or "A New Cereal," and also any information regarding it.

C. G. S.

Mysore, 18th November 1880.

NOTE.—We believe the seed of the *Sorghum Saccharatum* is not to be had anywhere here, but doubtless our correspondent would be able to get a small supply by applying to the Superintendent of the Saidapet Farm, Madras. Some useful information regarding the growth and culture of the *Sorghum* will be found in "The Saidapet Manual," p. 40.—ED., *I. A.*

INFORMATION WANTED.

TO THE EDITOR.

SIR,—A correspondent in Switzerland writes to me for the seed of the "Dschugara" or "Schugara," a forage plant for cattle. Could you inform me where it is procurable, or if it is known under that name in this country. Apologising for troubling you—

H. W. N.

NOTE.—So far as we are aware the plant is not known in this country by that name, and unless our correspondent can give us the botanical name, it is impossible for us to trace it.—ED., *I. A.*

DATE COFFEE.

TO THE EDITOR.

SIR,—With reference to a paragraph in your last issue about Date Coffee, will you kindly explain what is Date Coffee, and why was Bussorah selected for its manufacture? I thought dates grew only in Arabia.

AN INQUIRER.

NOTE.—The date tree is abundant in Persia, Arabia, Egypt, Barbary, and the adjacent countries, wherever there is sufficient moisture. The coffee is made from the stone or kernel.—ED., *I. A.*

JUTE.

TO THE EDITOR.

SIR,—Glad I am to see that Jute Mill shares are going up after their long depression, which must be giving comfort to the hearts of those holders who bought at or near par years ago.

But although there has been a marked advance with regard to the Barnagore, Budge-Budge, Seebpore and others, yet it is not so much as might have been expected in view of the great demand that must arise for gunny-bags consequent on the passing of the Grain Shipping Bill at home, whereby grain must be loaded in bags and not in bulk, as formerly. This must surely cause an immense sale of the stocks, and I should think keep the Mills fully employed at good paying rates.

I never doubted the ultimate success of such Jute Mills as were resting on good foundations, and now that they are emerging from their trials and troubles, they are showing that life which I was certain was in them, and which only wanted an opportunity to burst forth.

A. W. B.

November 23rd, 1880.

RED ANTS IN COFFEE.

(To the Editor of the Ceylon Observer.)

DEAR SIR,—Could any of your numerous correspondents suggest an effectual remedy for red ants in coffee? At low elevations and in fine coffee they establish themselves and rapidly spread from tree to tree, and entirely prevent the coolies doing any work in the neighbourhood of the trees affected. I have tried syringing the trees with carbolic acid and water almost strong enough to burn the leaves, but the ants do not seem to mind this in the least. I am frightened of fire, or I would try smoking them out, but I doubt whether even sulphur would do.—I am Sir, Yours truly,

INQUIRER.

Trevandrum, Travancore, October 14th, 1880.

II.

SIR,—In answer to your correspondent from Travancore who asks the best way to get rid of red ants in coffee, I advise him to put a blazing wisp of straw under the nests. I don't mean that a fire should be kindled, but the blazing wisp of straw be held for a little time under the nests. Unless in very dry weather there can be no danger in the above plan. I have tried burning sulphur, kerosine, carbolic acid, and hot water. Smoke is no good. Flame is the only thing. They can't stand a good flame. They find that uncomfortable.

PURE FLAME.

III.

SIR,—In answer to your correspondent from Travancore, unslaked coral lime thrown into the trees by hand, a couple of handfuls to a tree, will disperse red ants,—Yours faithfully,

H.

MANURING CINCHONA.

(To the Editor of the Ceylon Observer.)

DEAR SIR,—Referring to the subject of manuring cinchona and its results, there can be no doubt about it that digging in bulk (with half b. of artificial manure, poonac, castor, and bones per tree) has a wonderful effect upon the *growth* both of young plants which were "sticking" and the more mature four and five years old.

And the digging in of lime alone shews very sensible results; whether an increase of alkaloids accompanies the quickened growth can, I suppose, only be *proved* by analysis. Can you judge at all by the *taste* of a strip of bark? For I have found that covering of the stem of a *succirubra* cinchona tree with gunny bags to the height of five and six feet, has a marked effect. By taking a narrow strip of bark, half from below the sacking and half from above, and tasting both ends, you can tell which was under covering by the increased bitterness. Does this shew an increase of alkaloids?—Yours faithfully,

TASTE AND TRY.

October 22nd, 1880.

[Certainly, the taste is a fair indication so far as it goes: in very poor, or worthless barks there is scarcely any bitterness perceptible.—ED., *C. O.*]

MANURING CINCHONA AND CINNAMON.

(To the Editor of the Ceylon Times.)

SIR,—I have noticed in one of the local papers some remarks on the subject of manuring cinchona with an attempt to draw a comparison between the effects of that cultivation and similar experiments with cinnamon. The writer of those remarks laboured under the disadvantage of not being aware of the very different conditions under which the formation of the properties of the two barks takes place. In the one those properties consist of alkaloids deposited through the action of the roots and the sap in the other case the qualities for which the bark is valued, consist of an essential oil, in the formation of which the action of the solar rays is absolutely necessary. In the case of cinchona the de, osit of the alkaloids is hindered by too great an accession of light, whilst in the other case the formation of the essential oil of cinnamon on which the value of the bark depends, is only carried on by means of the solar rays. Cinnamon grown under deep shade possesses little if any flavour, for the reason that the absence of the action of solar light has deprived it of the essential oil in question. It is for this reason that what is known as jungle cinnamon is of so little value, that description of the spice is of precisely the same variety as the plants grown in the preserved plantations, having been propagated by means of seeds dropped by birds in the jungle, but having grown in the deep shades of the forest the bark has acquired no essential oil, and is therefore flavourless.

Now this being the case, it follows that the larger the surface of cinnamon bark exposed to the action of solar rays, the more essential oil will be formed within it, hence the use of suitable manures to aid the growth of cinnamon, tends to extend the surface of the plant, and the idea that manure produces a coarse bark, can only be justified where the soil is unsuitable to rapid growth, even with the help of manure. It is well-known to those few cinnamon cultivators who have given any attention to the subject that a great deal of the effect of high cultivation depends upon the kind of manure employed and the description of soil in which it is used. I may mention for instance that it is a great mistake to use stable mannure or the manure of pigs or any of the phosphates upon cinnamon grown in heavy stiff soil; on the other hand the greatest advantage will arise from using cattle manure, ashes or decomposed poonac on cinnamon growing in light or even sandy soil. In such cases the effect of manure is certainly not to produce a coarse bark, but on the contrary by causing the sticks or shoots to grow rapidly upwards to encourage the formation of a thin and delicate bark of highly aromatic property, provide it be grown away from heavy shade.

Not only is the use of manure of a proper description very beneficial to cinnamon, but I have seen the greatest advantage derived from loosening soil about the roots of cinnamon bushes.

CULTIVATOR.

SELANGOR AS A FIELD FOR PLANTERS.

(To the Editor of the Straits Times)

SIR,—I have often wondered why the sister State "Perak" should be more sought after as a field for planters than the State of Selangor, with its great, if not superior, advantages and its acres of beautiful virgin soil, and that, a great part of it, of a fine black and red loam nature and I should say certainly adapted to the growth of tobacco sugar, tapioca, &c. Inspection will, I am sure, do away with any question as to the land being suitable for the successful culture of the above-named products; the intending planter has only to be careful in his selection. As to that most important item towards the success of a planter, that is, the means of conveying goods to and transporting produce from his estate to a suitable market or for transhipment, I submit that the district of Klang, and the vicinity of its town Pencalian Batu, (Klang) the former head-quarters of the Selangor Government

offers the most, to say the least of it, encouraging advantages to intending planters. There are three steamers weekly keeping up a regular service between Singapore and Klang and *vice versa*, and every alternate week the *Pyah Pekhet* makes her usual trip from Singapore to Penang and *vice versa*, calling at all ports in the Native States. I am further informed that the Salangor Government is making a road direct from Pencallan Batu (Klang) to its present head-quarters at Kwala Lumpur; such a praiseworthy movement as this cannot be too highly estimated.

Labor and the means of procuring it may become a question with the intending planter; but I should anticipate no scarcity under this head as coolies arrive at "Pencallan Batu" by every steamer, and it would be a matter of very little difficulty to obtain through an agent in Singapore any quantity of coolies (Sinkies or new arrivals) from China, and who by the way, I think, are most useful men on an estate. Most of them are good gardeners in their own country, and from my little experience I am convinced as to the superiority of the Chinese as labourers, but would suggest a gang of Javanese and Klings working with them as having a most decided effect to keep them orderly. So much for the labor question. The intending planter has, I submit, only to keep his coolies under strict and just control, which will be effected in a great measure by paying their wages at stated and regular periods, to reap the benefits incumbent upon a well managed estate.

As regards materials for building purposes, &c., I can only state that the district of Klang offers peculiar advantages. The intending planter can put up his various sheds at quite a moderate cost as compared with Deli and other places in Sumatra. I have only to mention the low price of Attaps, $6 00 per 1,000, to prove the above. The Land Regulations issued and at present in force under the Selangor Government appear to be fair in their construction, but I should advise the intending planter to place himself in direct communication with H. B. M.'s Resident at Kwala Lumpur, and that gentleman will I feel sure be only too pleased to give every assistance to and encourage the legitimate and intending planter.—Yours faithfully,

CASSAVA.

Singapore, 29th September 1880.

THE SOIL OF FIJI.

(*To the Editor of the Ceylon Times.*)

SIR,—To those desirous of information about Fiji, the following analysis of a sample of soil, recently received from Mr. W. Fullingham Parr may be interesting. It is from Great Amalgam Estate where leaf disease first made its appearance in Fiji. The sample was taken from different depths, and represents the composition of the soil from surface to a depth of three feet.

	Per cent
Water expelled at 212 F.	3 990
* Organic matter and combined water	12·848
Peroxide of iron and traces of oxide of Manganese ...	6·020
Protixide of iron	·867
Alumina...	11 090
Lime	·199
Magnesia	·065
Potash	·096
Soda	·063
Phosphoric acid	·128
Sulphuric acid	·008
Chlorine	·026
Carbonic acid	Trace
Soluble Silica	·194
Insoluble silicates	64·386
	100 000
* Containing nitrogen	·201

The chemical composition of the portion extracted by acid is, on the whole, very similar to that of our Ceylon soils. The percentage of lime is low; but higher than in most of the Ceylon soils that have been analysed. The amount of potash is about the average of that in our own soils, while the phosphoric acid is higher than our average. The percentage of nitrogen is fair. The insoluble residue, freed from organic matter, differs from that in Ceylon coffee soils. In the latter there is a large percentage of quartz crystals, while that from Great Amalgam estate consists of white clay with no admixture of quartz crystals. Although there is less alumina in the acid extract, the soil is nevertheless more argillaceous than any of the Ceylon soils submitted to me.

In making this comparison, however, it is to be remembered that the Ceylon soil analysed within the last three years have been chiefly if not exclusively surface soils.

In the loose state of sample, the soil required nearly 40 per cent. of its weight of water for complete satisfaction, six samples of soil, from Windsor Forest Estate and neighbourhood, varying from very quartsy to fine dark earth, took respectively 17·7, 26 1, 30 1, 33 5, 35 6, and 37·1 per cent. of water for saturation.

The reaction of the soil was distinctly acid, the sourness probably being chiefly in the subsoil. For acidity an application of lime is the remedy, assisted by more efficient aëration of the soil by tillage.)

M. COCHRAN.

Gas Testing-rooms, Colombo, October.

PAPER-MAKING INDUSTRIES IN CHINA; AND CEYLON WASTE PRODUCTS.

(*To the Editor of the Ceylon Times.*)

SIR,—The Commissioner of Customs at Wuhu (China) in a report recently issued, states that paper is very extensively manufactured in the numerous little villages situated in the valleys among the hills about eight miles to the south-east of the city of King-hein. It is made from the bark called T'an Shu-p'i, the paper-mulberry tree bark, and wheat straw, which, after having been well washed and boiled with a certain proportion of lime is again washed, and then exposed to dry on the side of the hills. After this exposure, it is washed once more, and then pounded on a stone with a large wooden hammer. It is supposed to require 1,400 blows from this hammer to reduce it to the necessary consistency; after which it is removed to another building, and left to soak until it becomes quite a pulb, in a large eathenware vessel containing liquid glue made from boiling the branch of a tree called Yangkowt'eng, a species of hooked vine. This pulp is then put into a cistern of water, and well stirred up with a stout stick. A finely made bamboo frame, or a sort of long oblong sirve, is taken by two men, one at either end, and dipped twice into this liquid, which is made to run equally over the whole surface, somewhat after the manner in which a photographer allows the developing solution to run over his plate. By these means a tolerably even layer is left, which soon partially dries and forms the sheet of paper, which is removed by simply reversing the frame; as soon as a sufficient number of sheets have been made, they are taken to the drying room. This room contains a large brick oven, coated on the out side with lime, and built up to within a few feet of the roof. Upon the top of this oven the paper is placed in parcels of about a foot in thickness. until perfectly dry; after which sheet by sheet is damped once more, and while still moist is, by means of a soft brush, made to adhere to the sides of the oven for a short time, to undergo its final process of drying. It is then taken away to the packing room, and made up into bales weighing from 80 to 120 catties each, the catty being equivalent to 1⅓lb. avoirdupois. The largest sized paper is one *chang* (11⅔ feet) long, and is worth one dollar a sheet. This particular size of paper is made entirely from the "Tan-shu-p'i," but the smaller sizes are composed of a mixture of the above-named bark, or the bark of the paper mulberry tree and wheat straw. This paper is known by the name of "Suan-chih," and is considered a good quality paper in the Chinese markets.

Why should not a similar process answer with the waste products of Ceylon, such as:—managrass, cinchona, and cinnamon sticks, &c., &c.

YANGKONT'ENG.

Colombo, October 6.

The Indian Agriculturist.

CALCUTTA, DECEMBER 1, 1880.

TEA STOCKS: INDIA A MARKET.

FEW subjects are of more interest to those concerned in tea, than that of the state of stocks in London. Stocks which were 13,300,000lbs. on 31st October 1879, were 17,000,000lbs. on the same date this year; deliveries for consumption during the first ten mouths of the present year were 33,000,000lbs as against 29,500,000lbs for the corresponding period of 1879, an increase of 3½ million pounds or nearly 12 per cent while imports were 34,023,941lbs in 1880, against 27,8..,554lbs in 1879, an increase of 6,167,387lbs or over 22 per cent. Hence the unhealthy state of stocks. It is no doubt a gratifying fact that consumption has made such strides, and it is re-assuring as regards the future: but there is another

feature which we shall notice by and by. The following table gives the average consumption of the first ten months of each year from 1878 to 1880, and the number of month's stock on hand on 31st October :—

	Average monthly consumption. lbs.	Months' supply in stock.
1878	... 3,000,000 ...	... 3½
1879	... 3,000,000 ...	... 4½
1880	... 3,300,000 ...	... 5⅛

The average increase in consumption would appear from this to be at the rate of 5 per cent. Taking a longer series of years into consideration, however, we find that consumption has steadily increased at the rate of about 12½ per cent. This is very encouraging, and there are not wanting signs that this average ratio is gradually increasing. When we come to look at production, we find the true clue to the present depressed state of the market. The imports in London during the last three years have increased at the rate of over 16 per cent per annum, thus much more than keeping pace with the consumption; and until consumption exceeds production, we need not look for any material change in prices. There are two ways whereby stocks can be reduced, *viz.*, by confining manufacture for a few years to the very finest qualities only, and by finding new markets for our produce. Both are within the reach of possibility, and both are calculated to effect a cure for the present state of the tea market. On the first mode we have on a former occasion offered a few remarks, and shall therefore now look into the second. Efforts are being made, and not without fair prospects of success, to open out a market for Indian tea in Australia, and a local contemporary has a letter suggesting Canada as a new field; and doubtless other places will gradually be considered as within the reach of Indian tea. We, however, desire to draw attention to a market much closer to our doors, and that is India itself.

The caste prejudice which prevents natives of this country indulging in European diet, is entirely wanting in regard to tea. Our servants all use it, and so do all natives when they can contrive to get it cheaply or for nothing. We are all familiar with the request for a little tea when any of our servants are sick. We have therefore a good basis on which to go. The only obstacle in the way of this stimulant becoming a common article of diet is the poverty of the people. From this we do not wish to argue that we should offer them our tea at half price because they cannot afford to pay the full price. There are other ways of meeting the poverty of the people. Tea is a luxury to them, and so it would be to the great bulk of the people of England if they could only purchase it in large quantities. If this be true with reference to the people at home, how much more true is it of the poorer classes here, who for all practical purposes constitute the entire population. Now to meet this difficulty at home, tea is sold in small quantities. The poor people who cannot afford to purchase this article in large quantities would never taste it were this concession not made. And they can purchase as small a quantity as a quarter of an ounce. This is exactly what we want here. We could not very well sell such infinitesimally small quantities, but there is no reason why a cheap class of tea should not be made up in one ounce packets to meet this demand. Large quantities of China tea arrive in India every year, the average annual imports being over 2,000,000lbs., and if the Indian tea business were only conducted so as to meet the wants of the poorer classes very little tea would come from China. This latter tea is freely purchasable in 1 and 2 ounce packets, but if one wishes to buy Indian tea he must purchase at least one pound. At first, broken teas and dust might be placed on the Indian market in this way, and as these low qualities represent about 10 per cent. of the total export to Europe, it will easily be seen what a relief this would afford the London market. If Congous could also be disposed of in this way, the relief would be equal to about six or seven million pounds per annum. The tea could be sold at three pice per ounce, which would more than cover value of tea and cost of wrapping up in small packages. Congous could be sold at one anna per ounce, in the same way. If the mass of the people would only be induced to turn their attention to tea, the consumption would be enormous, one ounce per annum per head representing fifteen million pounds. We trust the tea interest will think well over this, as nothing would bring such certain and speedy relief to their financial position.

TEA COOLIES IN ASSAM.

THE Resolution of the Government of India on the Assam Labour Immigration Report for 1879 has just been published, and as it contains much matter of interest to a number of our readers, it may be worth while briefly to review it. The total coolie population of Assam on 31st December 1879 amounted to 148,104 souls. Against this the figures for the three previous years (1876-78) were 135,807; 157,074, and 178,095 respectively. These three years show a steady increase in the total labouring body, though the importations during 1879 were far below those of the preceding year. The total importations for the year, including coolies not under the Act (VII. B.C. of 1873), were 24,712 persons as against 43,061 in the previous year. This gives a decrease of no less than 42 per cent., and we are told it was large under every class, including contractors' coolies, those recruited by garden sirdars, and adults and others not under the Act. This circumstance is attributed to—(1) the good harvests in the recruiting districts, which made the coolies unwilling to emigrate; (2) the reluctance of managers to accept recruits from the North-Western Provinces, owing to the mortality amongst this class in the previous year; and (3) in some measure, to the more economical working of all gardens consequent upon the fall in the price of tea. But, viewed in the abstract, this heavy decrease is apt to mislead, and it is therefore worth mentioning that it appears generally o have been the case that the importations of the year fell short of the demand. What is sadly wanted in Assam, however, at present is, as we have often urged—improved communications. Probably nothing will do more to cheapen, and therefore to increase, immigration into Assam than this. The subject has been discussed on and off for the last eight years, but as yet no practical results have ensued. Still, we live in hope, and the past year has perhaps brought us nearer to a tangible solution of the difficulty than has ever hitherto been the case. The subject of improved communications has, in fact, received considerable attention from the Chief Commissioner, and we see that Sir Steuart Bayley has recently submitted to Government a comprehensive review of the whole question of establishing an accelerated steam service on the Brahmaputra; and in the event of such a service being set on foot between Dhoobree and Gowhatty, he has asked the Government of India for aid so as to enable him to extend it higher up the river. This request, we are told, is "still under consideration." It will be remembered that the members of the Assam Tea Districts Association memorialised the Government in the course of the year, on certain matters connected with their industry. We now learn that on receipt of their petition the Government of India consulted the Chief Commissioner of Assam and the Government of Bengal on the desirability of appointing a Commission to investigate both the limited question of the working of Act VII. and the more extensive subject of free immigration generally. Concerning these the Report tells us :—

"It has been determined that these two questions shall be kept entirely distinct, that a Commission, whose duties will be confined to the first question, shall be appointed; and that this Commission shall be required to frame a draft Bill for the amendment of the Labour Law. The precise constitution of the Commission, and whether it is to be a stationary or a peripatetic body are points which have yet to be determined."

But this is not all. There are several other matters which may appropriately be brought to the notice of the Commission when it has assembled; such, for instance, as the importation of coolies under verbal engagements, the proposed extension of the term of contract from three to five years, the suspension of the contract during imprisonment, the provisions of the law regarding the diet and wages of immigrants, the operation of Act XIII of 1859, &c., all of which are referred to in the present Report. As we stated a day or two ago the Commission will sit during the present cold season.

We now turn to matters relating to the general welfare of the coolies during the year under review. We are glad to note some improvement in the matter of desertions, though the figures are still very high. The number of desertions in 1879 were 5,885, as against 7,515 in the previous year. Upon this subject we are informed that—

"The Secretary of State has expressed his concurrence in the view stated by the Government of India in remarking on last year's Report, that no special proceedings need be taken by the Government to check desertions so long as the tea-planters do not seek its intervention. But the Governor-General in Council agrees with the Chief Commissioner that the systematic enticement of coolies, alleged to have occurred in south Sylhet, is a very different matter from mere ordinary desertion, and that, if it be true, the offenders should be punished according to law."

It is difficult to assign any particular reason for the desertions, beyond the comparative ease with which they can be effected and the relative difficulty of detection. But we suspect there is also some connection between the death-rate and the percentage of desertions though the affinity probably is not close.

As regards the mortality it is satisfactory to observe that in the labour districts generally there was a very considerable decrease amongst adults. The total deaths were 6,695 against 8,072 in the previous year. But the actual improvement was confined to the Act VII. coolies, who shewed a diminution in every district. Among non-Act coolies the death-rate, though not in itself high, shewed a slight increase, owing to a somewhat greater mortality in the districts of Cachar, Durrung, Nowgong and Luckimpore. A comparison of the death-rate in the different districts with the proportion borne by newly imported coolies to the total labouring population, indicates, as was the case last year, a general connection between recency of arrival and mortality. The first four districts (excepting Kamroop which is comparatively insignificant) both in respect of mortality and importation, are Nowgong, Durrung, Sibsaugor, and Luckimpore, and the last two Sylhet and Cachar. Looking at the statistics it is noticeable that the exceptional mortality which occurred amongst the Madras coolies in 1877 has not recurred, and that the death-rate amongst Act VII. coolies from the N.-W. Provinces and Oudh and Behar has greatly diminished. In the case of coolies from the last-named localities the improvement is no doubt due to the order passed by the Chief Commissioner (in consequence of the very serious mortality which occurred in 1878), prohibiting the introduction of unacclimatized coolies into certain gardens in Cachar. This measure seems to have had good effects in various ways, and the Government of India agree with Sir S. Bayley that the province of Assam "is not unsuited to labourers from Madras and the valley of the Ganges, provided that due care be taken to prevent the emigration of coolies reduced by want, and to supply new arrivals with a suitable diet."

But notwithstanding the general improvement in the death-rate amongst coolies from the N.-W. Provinces, the mortality in particular districts (Durrung, for instance) and in certain gardens was lamentably great. It is presumed that the causes of this will be fully investigated, if not already ascertained. In two gardens, in the Nowgong and Luckimpore districts, the death-rate of the second half of the year was 16·52 per cent. and 39·21 per cent. respectively, the explanation given in both cases being that the coolies received were "inferior in physique." We do not think this explanation by any means adequate or satisfactory, especially as regards the extraordinary figures (39·21 per cent.) for the Seelonee garden. We have but to compare it with the average mortality of the district, 5·73 per cent., or, even with the average of the whole of the seven districts, which was under 6 per cent., to see how anomalous the figures are. The matter should be inquired closely into. There have been complaints recently of the importation into Assam of an inferior type of coolies but we think the Government are right in repudiating any responsibility therefor. As the Chief Commissioner of Assam expressed himself, in a recent report on Inland Emigration, "the responsibility of selecting physically fit labourers ought not to rest upon any Government officer, but on the agents and representatives of the Employers," and we observe from a recent Calcutta *Gazette* that Sir Ashley Eden entirely concurs in this view.

From deaths we turn to births. The total number of births reported was 4,996 or a decrease of 510; but there is reason to doubt whether all the births have been registered. Even admitting that, however, it seems almost certain that the births are largely exceeded by the deaths amongst the general coolie population. The average number of women in the province increased during the year, but the proportion of births to the number of women varies so much amongst different classes and different localities (from 4·13 to 10·01 and 15·78) that, we are informed, no certain inference can be drawn from the figures. Infant mortality was less severe, falling from 1,776 to 1,472.

The number of tea-gardens during the year rose from 913 to 1,040, though the greater part of this increase is nominal, being merely the result of a revised classification. The duty of official inspection of gardens seems as a rule to have been sufficiently performed, there having been in all 804 inspections against 636 in 1878. These figures appear more favorable when we remember that they refer only to gardens employing Act VII. coolies. There are a large number of gardens in the districts of Nowgong and Durrung employing coolies not under the Act, and which, therefore, were not inspected. But "the Governor-General in Council concurs in the opinion of the Chief Commissioner, that opportunity should be taken to visit such gardens, even though the law does not at present make their inspection compulsory." During the year 2,457 acres were taken up for cultivation by time-expired labourers in the different districts, excluding however Sylhet and Kamrup, where, for reasons not stated, no information is available. This tendency on the part of the coolie population to settle down in the province is of interest and importance, and we are glad to see it is receiving attention. The Governor-General in Council asks for statistics to be incorporated in the next Annual Report. The Resolution we are noticing concludes with a paragraph on the Dhubri Immigration Report on the desirability of collecting statistics regarding the free immigration into the province. It is, we are told, necessarily a matter of much difficulty to ascertain the number of labourers emigrating to Assam otherwise than under supervision; but it is intended during the current year to attempt to register the free immigrants at Dhubri for the Assam Valley, and at Bhairab Bazar for the Surma Valley. If the attempt prove successful, we are promised details in the next Report.

THE FIVE YEARS' AGREEMENT.

It is matter of regret that the proprietors of tea in Cachar, Assam, and Sylhet, cannot contrive to agree as to what they want done with Act VII, of 1873 (B.C.). For years they have been agitating in a spasmodic and disjointed fashion, letters now and again appearing in the Calcutta papers. But no sooner did a letter appear complaining about a grievance, than a rejoinder, also from a planter, appeared disputing the ground taken up by the former writer. Commissions have from time to time been appointed to bring all these matters to a focus with a view to submit a united memorial to Government, but the result has usually been *nil*, principally from want of agreeance among those interested in tea. Notwithstanding the protest of our esteemed correspondent in our October issue, we must adhere to the view that we have taken—that there is a diversity of opinion on most of the points considered grievances. On none of these does there seem to be such divergence of opinion as on the propriety of adopting the five years' agreement. At present the term of agreement is three years, and a large majority of those interested in tea are in favor of extending this term to five years. There is, however, a minority who manage to make themselves heard and who do not approve of the proposed change. To us it seems indisputable that the five years' term should work more satisfactorily for the planter, while being equally fair to the coolie. The great stock argument against the proposed change is in speedy process of being annihilated. It was said that the length of the term would tend to frighten labourers from coming to the tea districts at all; but this—never a good argument—is absolutely without point in the present day. The improved communications between the recruiting districts and Assam, are leading to large numbers of labourers finding their way up the valley without any recruiting at all. During the last five years, from 1875-76 to 1879-80 inclusive, the numbers of this class registered at Dhubri each year have been 2,889; 3,719; 9,870; 10,270, and 7,957 respectively. This will very speedily place the planter in a position to dictate terms, and will make a more lengthy engagement quite possible. Cachar and Sylhet will by

and by have their communications improved in like manner, and hence this objection against the five years' agreement falls to the ground. We do not argue that the planter should insist on it, because he is now in a position to do so. This would be unfair. We are, however, convinced that it would be better for the coolie as well. It may be urged that the bonus he gets for re-engaging at the end of his term of three years, would under the new arrangement not be at his disposal for five years. This is beside the question, as the bonus system is itself an anomaly and will speedily have to be abolished if the industry is to survive. Under the present depressed state of the industry, all such unnecessary expenses will have to be excised. The advantages of a five years' term as against a three years' are many, the principal one being that during the long currency of the agreement the labourer gets attached to the estate and as a rule will settle down on it as a permanent labourer. There are of course many other advantages which are self-evident and need not be enlarged on here. It is worthy of note that the five years' term is in force with regard to coolies forwarded to the West Indies and to other colonies, and the only difference between the two forms of agreement lies in the fact that the Colonial Government is bound to bring the coolies back to the port from which they started. Such an arrangement is unnecessary with reference to inland emigration, as the labourers can easily find their way back to their homes if so disposed.

RICE MILLS IN RANGOON.

THE rice trade may be fairly called the most important, and perhaps the most lucrative trade in Rangoon ; there being no fewer than eighteen firms engaged in milling rice, while four new mills are being built. Those at present working are as follows :—

Messrs.	Bulloch Brothers & Co.,	who	own	four	rice	mills.	
„	W. Strang, Steel & Co.,	„	„	1	„	„	
„	Rowet & Co.,	„	„	2	„	„	
„	Mohr Brothers & Co.,	„	„	2	„	„	1 building & 1 working.
„	Todd, Findlay & Co.,	„	„	1	„	„	
„	Schumacher & Co.,	„	„	1	„	„	
„	Bosworth & Co.,	„	„	1	„	„	
„	Gerber, Chestien & Co.,	„	„	1	„	„	
The	Bombay and Burmah Trading Corporation, Ld.,			1	„	„	
„	Kruger & Co.,	„	„	1	„	„	
„	Stohman & Co.,	„	„	1	„	„	
„	Mower, Burn & Co.,	„	„	1	„	„	
„	Dickmann, Burckhausen & Co.,	„	„	1	„	„	
„	Burjarjee & Co.,	„	„	1	„	„	
„	Leak Chin Seng & Co.,	„	„	1	„	„	
„	Kho Khin & Co.,	„	„	1	„	„	
„	Koo Kwet Nee	„	„	1	„	„	
„	Moung Pho Mien & Co.,	„	„	1	„	„	
	NEW MILLS BUILDING.

„	Mohr Brothers & Co.,	„	„	1	„	„	
„	Ainsley, Warren & Co.,	„	„	1	„	„	
„	Hashimariff Brothers & Co.,	„	„	1	„	„	

With the exception of three at Kemendine, and one at Dalla, all these mills are situated at or near the Poozoundoung creek which is the great market for paddy. The paddy brought to Rangoon is divided into three principal kinds known as *Ngatsaing*, *Nghchouk*, and *Boyoot*. Of these the *Ngatsaing* paddy is by far the best ; it has large broad grains, dark in colour with a fine pearly kernel. The *Nghchouk* has light coloured grains, long and narrow ; often the husks are only partly filled which makes it less profitable to mill than the Ngatsaing paddy. The *Boyoot* has small grains, in appearance like *Ngatsaing* only smaller, and has a beard-like barley. The Burmese prefer the rice made from *Boyoot* paddy to any other.

The paddy is brought down the river in boats by Burmese boatmen, who being shrewd fellows, and delighted at the opportunity of doing a little cheating, require no small amount of tact in dealing with them. In this respect, however, some of the merchants are not much behind them, and altogether the paddy trade cannot be considered a very straightforward business, as may be gathered from the remarks of the late Chief Commissioner when commenting on the evidence adduced in the case of Mower, Burn & Co. *v.* Burjarjee, in which he strongly deprecated the practices of using spring bottoms to the baskets, scooping, &c., &c.

The paddy is always sold by measure at so much per 100 baskets. A basket is supposed to contain fifty pounds weight of paddy, and should be 15 inches diameter by 15 inches deep. The price per hundred baskets varies from Rs. 90 to Rs. 120 ; generally it is about Rs. 95. The paddy is measured by Burmese measuremen who are paid so much per hundred baskets by the boatmen ; but the former are appointed by the mill-owner, who sometimes exacts a certain proportion of the earnings as payment for the privilege. During spring tides when paddy is plentiful, the boats generally come direct to the mills to sell their paddy ; but when paddy is scarce, the boats are met some distance up the river by cargo boats, and the paddy when purchased is transferred to the cargo boats and by them brought to the mills. In all these transactions Burmese brokers are employed and paid so much for every hundred baskets of paddy they obtain.

Now, to understand how the paddy is made into rice, let us suppose that a boat of paddy has arrived at the mill, and follow it through the different processes. After being measured by the measuremen, it is carried by coolies into the godown, or, if the paddy is coming in slowly, directly into the mill. At the commencement of the year these coolies contract to land all paddy for that year at so much per 100 baskets. The paddy having been emptied into a hopper in the lower floor of the mill, is, by means of an elevator, lifted to the top storey of the building, where it is generally sifted either in a reciprocating or revolving sifter to free it of any dust, stones, sticks, &c., which may be mixed with it ; sometimes this preliminary sifting is omitted, but it should always be done as it greatly saves the mill-stones. After being sifted, the paddy passes through wooden pipes to the hulling stones on the floor below, for the purpose of getting the husk removed. Till lately this operation consisted of passing the paddy between two circular pieces of hard gritty stone, about four feet six inches in diameter, and about four or five inches thick, the bottom stone being fixed, while the top one, being suspended by a rynd on the top of the spindle, revolved over the bottom or fixed stone, at a speed of about 200 revolutions per minute. The paddy being run into a hole about one foot in diameter in the top stone, found its way between the two stones, and before escaping at the edges most of the grains thus had the husk removed. Within the last three years, however, a great improvement on the old plan has come into use, which, although not at all popular at first, has now proved itself to be far superior to the old method in every respect. It is much cheaper in first cost, turns out a larger quantity of rice, and much better quality, and gives much less trouble as it will run for three or four weeks without attention, whereas the old stones had to be dressed every three or four days.

In the new plan the stones are replaced by cast iron discs, and instead of the bottom stone being fixed and the top one made to revolve, the reverse is the case, for the bottom stone revolves and the top one is fixed. The bottom disc being firmly secured to the spindle, is much more steady in its action than the old-fashioned plan where the top stone merely rested on the spindle and depended entirely on its own weight for steadiness. The working surfaces of these discs are covered with a layer of a sort of artificial stone known as Carbutt's cement which consists principally of a mixture of emery powder and magnesia, applied in a soft state ; when dry, it forms a very hard durable material much superior to stone, which indeed it excels in every respect but one, *viz.*, that it is affected by damp and is apt to warp and come off if not protected and kept warm when not in use during the rains. The surfaces of the stones used in hulling rice are flat, not grooved as in mill-stones for making flour. In passing between the two stones, the husk of the paddy is rubbed off, and the rice and husk come out at the edges. This is next elevated to the top of the mill by means of another elevator, and passed over a winnowing machine to remove the husk. The winnowing machines usually consist of three sets of revolving fans, placed one above the other, the rice passing in front of each : any rice which may be blown out is collected and passed over another set of fans.

The rice after coming from the farmers, is what is known as "five part" or "cargo rice." It consists or is supposed to consist of five parts of rice to one of paddy, and contains a little broken rice. In some mills this is removed by sifting, but since the introduction

of the new hulling stones, the proportion of broken has been so much reduced as to make it hardly worth taking out. The rice, if intended to be shipped as cargo rice, is next run into a hopper which opens into the bagging shed where it is weighed into bags of 225lbs. or 230lbs. each; these on being removed from the scales are examined by the party for whom the rice is being milled, and, if not rejected, are sewn up. The sewing is generally done by Burmese women and girls who are paid so much per 100 bags. The bags if not intended for immediate shipment, are now removed to a godown and stowed away; this work is done by coolies who contract by the year to stow away and ship into cargo boats when required at so much per 100 bags. So much for cargo rice in which the operations are few and simple. Not so however in making white rice, *i.e.*, removing the inner skin of the grain and making it fit for table use.

If the rice is intended for white rice, instead of running down to the bagging shed after being winnowed, it is again elevated to the top floor of the mill where it is passed through two, three, or even more sifters to remove as much of the paddy as possible. The sifters used in this operation are generally reciprocating and the wire netting of different degrees of fineness. After leaving the sifters the rice passes to the white rice stones, of which there are two kinds in general use. One kind, perhaps the more used of the two, consists of a conical drum of wood or iron about three feet deep and five feet diameter at the top, and four feet nine inches diameter at the bottom; this is fixed on a vertical spindle. The sides of this drum or stone as it is called are covered with the Carbutt's cement before described. Round this drum and fixed concentrically with it is a framework of wood or iron to which is fastened a fine network of steel wire; this forms a "casing" which is "set" so as to leave a space of about ⅛" to ¼" between the stone and the network all round. This outer drum or "casing" is a fixture, but the stone revolves inside it at a speed of about 200 revolutions per minute. The rice is fed in on to the top of the stone, and, finding its way down between the stone and the casing, is spread out and rubbed as the stone revolves, the skin, in the form of dust, escaping through the network and the rice getting out below. This operation is generally repeated twice, to bring the rice to its proper degree of whiteness. The other description of white rice stone is much the same, only the stone is made about eight feet in diameter while not more than twenty inches deep, and parallel instead of conical, and on the whole they appear to be the best. The wire netting only lasts a short time and is the most expensive item in working white rice stones. Some parties have tried the plan of making the casings of alternate segments of Carbutt's cement and wire netting, and even leather has been tried, but it is believed that this plan causes more rice to get broken, though it makes the stones more easily driven. White rice stones require great power to drive them, probably not less than from 150 to 120 Indicated Horse-power each. Generally, a mill will make about 500 bags of white rice per day, while of cargo rice, with twelve hulling stones, from 2,500 to 3,000 bags can be made per day. The white rice after leaving the second stones is again elevated to the top of the mill, and sifted to remove the broken grains which generally amount to from ten to fifteen per cent. This broken rice is winnowed and bagged separately. The whole rice is then passed through another sifter to remove any grains of paddy which may be left in it. It is next passed over a winnowing machine to clean it from dust and bagged.

White rice is generally known by three qualities, 1st and best Europe, 2nd Straits, 3rd Bombay. The quality depends on the degree of whiteness, the kind of paddy from which it is made, and the amount of "broken" which it contains. In some mills the rice before being bagged is passed through a polisher of sheepskin to smooth the surface and give it a pearly appearance. The dust or skin of the rice, which passes through the casings of the white rice stones, is sifted to remove any broken rice it may contain, and is then sold for feeding cattle, pigs, &c., and, by the Burmese for curing fish. It appears to be the most nutritious part of the grain, and generally fetches from Rs. 20 to Rs. 45 per 100 baskets. In making white rice, a considerable amount of skill is required in getting the necessary whiteness without breaking too much. The engines employed in driving the rice mills in Rangoon are with a single exception horizontal and generally arranged to work condensing or non-condensing; in most of the large mills the compound principle has been introduced.

The husk of the paddy after being removed by the farmers, has been, and in most mills still is run into the creek or river by means of a shoot in order to get rid of it. For some few years past attempts have been made to utilize it for generating steam, but till lately they have met with only partial success in practice. Of late, however, great improvements in its use have been made, and it probably will not be long before it is universally utilised. The great difficulty in burning paddy husk is not the trouble of getting it to burn, but of getting the ash removed from the fire. The first attempts attended by anything like success were made by Mr. C. R. Cowie, whose apparatus was at first a modification of the "Regenerative Gas Furnace" invented by the famous Mr. Siemens, in which the fuel is first converted into gas and then burnt by mixing it with air. But after an explosion of gas, by which Mr. Cowie himself was injured, the gas principle was abandoned, and the more manageable plan of burning the husk on a grate inclined at an angle of about 45° was adopted. In this apparatus, for which Mr. Cowie holds two patents, the fresh husk is fed by a hopper into the furnace at the top of the slope, and as it burns it slides to the bottom and is there raked away. This apparatus was erected and tried at several mills, but owing to proper precautions not having been taken in protecting with brick-work the fronts of the boilers from the impact of the fierce flame, many boilers were burnt, and the mill-owners having taken a scare, the apparatus was condemned and discredit brought on a deserving invention. Since that time Mr. Cowie has employed egg-ended boilers where his apparatus is used, and probably from this cause alone his invention seems to have made little or no headway. The small proportion, and inefficiency of heating surface, compared with the weight and bulk of egg-ended boilers, together with the large quantity of water they contain, must always place them far lower in the scale of efficiency than boilers of either the Cornish, Lancashire, or multitubular types. Besides high pressures seem now to be the rule, and to save weight, it is of course desirable to keep the heating surface as large as possible in proportion to the bulk of the boiler.

Shortly after Mr. Cowie's patent was taken out, two other plans of burning husk were patented, *viz.*, that of Mr. Leybourn of Messrs. W. Strang, Steel & Co., and that of Mr. Pitt of Messrs. Mower, Burn & Co., Dalla Rice Mills; but as both of these employ inclined grates set at an angle of about 45°, Mr. Cowie considers them to be infringements of his patent, and Mr. Leybourn has submitted to him, while about the other the question is still pending. Mr. Leybourn's patent consists in using inclined grates set like the capital letter V inverted inside the flue of either a Cornish or Lancashire boiler. The husk has to be shovelled in by hand, and the ash is raked away at the bottom of the two slopes. So far as generating steam is concerned it seems to give good results, but the great labour in firing which has to go on incessantly, is the great obstacle to the success of this or any other plan by which the husk has to be thrown by hand into the furnace. In Mr. Pitt's patent there are two inclined grates set like the letter V under a Lancashire boiler; the husk falls into the furnace at the top of each slope through a space left for the purpose between the grate and the boiler. The two inclined grates do not meet at the bottom, but are about ten inches apart, and under them, so as to form a trough, is an arrangement of revolving grates by turning which the ash is allowed to fall through into a wagon placed to receive it, and is then thrown into the river. This plan seems to have been pretty successful, but is objectionable on account of the fire being placed under the boiler so that the greatest heat strikes the shell and causes great risk of burning. This indeed once took place at Messrs. Mower, Burn & Co.'s mill, where one of the shell-plates was burnt and a disastrous explosion narrowly escaped.

A great improvement, which however has not been patented, was made on this apparatus by Mr. Coath, who, in order to avoid the objection of firing the shell of the boiler, built a fire-brick chamber at one end, and placed the inclined grates inside this chamber. The top is formed by a fire-brick arch, and the husk is fed into the furnace through a number of holes in this arch; about four inches square and six inches apart, arranged so as to deliver the husk on to the top of each inclined grate. This furnace is the most successful which has yet been used. Its success however is mainly

due to the use of the fire-brick arch; for, after the fire has been burning a short time, the bricks become a white heat the radiation from which at once ignites the fresh husk as it comes into the furnace, and so entirely prevents the fire from burning dull through being smothered with fresh husk; for this reason the fire-brick chamber seems essential to success. Mr. Coath also employed a multitubular boiler like a locomotive boiler without the fire-box, the only heating surface being the tubes through which the flame passes once and then up the chimney. This boiler is seven feet in diameter and eight feet long, and contains 250 tubes, two-and-a-half inches diameter outside. It gives as much steam at 100lbs pressure as a Lancashire boiler seven feet diameter and twenty-five feet long does at 60lbs pressure. For burning paddy husk this boiler possesses many advantages; for, by splitting up the flame, as is done in passing through the tubes more heat is utilised and little passes into the chimney. Besides, the metal of the tubes being very thin, allows the heat to pass through more freely than through a plate. The first cost and freight of a boiler of this description is very much less than for a Lancashire boiler of equal power, and, where fresh water can be always obtained, these boilers give no trouble; but where river water has occasionally to be used, they are not to be recommended. Boilers like this, but fired under the shell, have been in use at Messrs. Gerber Chrestien's mill at Poozoundoung since the mill was built, and appear to be very efficient. This year Mr. Murdoch, of Messrs. Rowet & Co., has erected a furnace for which he has obtained a patent. He uses a fire-brick chamber built in front of the boiler and flat grates; the husk is fed into the furnace through holes in the arch, in the form of a shower, and becomes ignited as it falls, the ash being discharged through doors in the bottom which may be opened at pleasure. From the highly satisfactory results obtained and the elaborate manner in which Mr. Murdoch is carrying out his ideas, it is probable that, as a thoroughly practical and manageable plan, this will surpass all the others. If this plan of using a fire-brick chamber and holes to feed the husk thoroughly were adopted in Mr. Leybourn's patent, the firing difficulty would have been overcome and probably as good results obtained as any other.

The mills at Rangoon are generally managed by engineers who are as a rule well paid and, considering the importance and somewhat arduous nature of their duties, this is necessary. Some firms employ a miller in addition to an engineer, but this plan can hardly be considered as good as having an extra engineer; for, after becoming acquainted with the milling, the one can take the other's place,—a very important matter in the busy season when night work has to be done. The mills generally start at day-light and, all going well, continue working till nearly dusk. The labourers are nearly all natives of India, the firemen, engine-drivers, and mill men who have anything to do with machinery are generally from Chittagong, and the stone-dressers, paddy coolies, and boatmen from the Madras coast. On the whole they are well paid, the firemen getting from Rs. 18 to Rs. 25 per month, the engine-drivers from Rs. 35 to Rs. 50, and the stone-dressers from Rs. 20 to Rs. 40, while ordinary mill men get from Rs. 14 to Rs. 18 per month: all are provided with houses. Many of the mills are built of brick, but of late years iron and timber have become more common. Unless the mill-owners intend to ship the rice themselves, the rice is generally sold before it is milled, nearly all business being done by contract.

EDITORIAL NOTES.

In consequence of the many holidays, the usual monthly General Meeting of the Agri-Horticultural Society of India did not take place in October. The November meeting, however, was held as before, in the Metcalfe Hall, last Thursday. A report of the proceedings will be given in our next number, as usual.

AGRICULTURAL prospects throughout the country may be said to be generally good except in some districts of the N.-W. Provinces and Oudh which we must refer to in a separate paragraph. In Bengal harvest operations are now progressing and the yield will be perhaps above average. No rain, except a slight shower in one district, is reported as having fallen throughout the week ended 20th ultimo, and the cold weather has everywhere begun. Crop prospects continue good all round, and prices are falling in many districts. The last accounts from Bombay report slight rain; the autumn harvest is still being gathered and the spring crops are in good condition. In Madras and South India generally prospects remain satisfactory, and standing crops are doing well. The monsoon in most parts has set in with a heavy fall of rain. The rainfall this year is anticipated to be above the average, and ryots are busy in their fields. The want of rain is however felt in parts of the Deccan. Rain was wanted in the Punjab in the first half of November, but the heavy falls that have since taken place in Upper India generally, have had a beneficial effect, and prospects are reported to be fairly favourable. In the Central Provinces the *kharif* crop has been pretty generally gathered in and the yield is considered fair. *Rabi* sowings are now over, and the weather has been favourable. In Assam and in most other provinces and states prospects remain satisfactory.

As regards the North-West Provinces and Oudh the state of the weather during the past month has been anything but favourable, and the outlook for the crops is gloomy. The future prospects of the *rabi* crop now depend entirely upon the Christmas rains. If these are good and general, the cultivators, except in certain districts, may yet pull through, but if these fail there must undoubtedly be widespread distress. It is satisfactory to see that the local Government are alive to the danger. Last month we mentioned that *kutcha* wells were being dug for the benefit of the ryots. Further measures to alleviate distress have since been undertaken, and all the sanctioned masonry and earth-works on the various main and distributory channels of the Lower Ganges Canal is being pushed on vigorously, thus affording employment to labourers seeking work. In Rai Bareilly, where the distress is worst, it was estimated that only one-third to two-fifths of the ordinary area would be sown. A fortnight ago an Allahabad contemporary wrote :—

> In the bad tracts the people distinctly declare that the situation is worse than in 1877. Throughout the district the cattle are being foddered on *babul* and *sirsa* leaves, and withered rice, though this will not hold out much longer. The water in ponds is scarce and foul, and the cattle have to be watered from the wells. The condition of the people is gradually getting worse. Severe distress is probably imminent, and the people will not be able to manage much longer without the relief-works, which the local Government has sanctioned in advance.

Since the above was written, however, there has been some rain, which, though not nearly as much as is required, has not been without effect. A "competent authority" wrote to the *Pioneer* a few days ago, with reference to the recent fall of rain :—

> "If we get about as much more, and it is general, we should go up to nearly the full *rabi* area, and three-fourths probably of the threatened distress would disappear. For it comes just at the right time, when a really good effort is being made by people and owners, and Government itself, to get the *rabi* in. Sowings can go on well to about twelve days hence, and will be carried on, though exceptionally late, to the middle of December."

But we are not inclined to place much faith in the roseate view taken by this "competent authority." He is probably a Government official, and in that case it is easy to understand his writing thus. There is no doubt, however, that the late heavy and pretty general rains in Upper India—which, it may be worth remarking, were synchronous with a fall of snow along almost the whole range of the Himalayas,—have resulted in an altogether more hopeful feeling for the fate of the winter crops, and *rabi* sowings are still being attempted. But it must not be forgotten that except in Kairagarh, parts of Arail, and parts of the trans-Ganges Pergunnahs there has been no *kharif* to speak of. In the best tracts we hear there will not be more than a six-anna crop all round. Distress in a greater or less degree is therefore inevitable, and indeed is already taking place. It remains to see how far Government will exert themselves to successfully combat the evil.

CHEESE-MAKING is a branch of agricultural industry altogether unknown in the majority of districts, and but imperfectly understood in any part of India. Yet there seems no reason why it should not be successfully practised. Looking over the lately issued annual report of the Government Experimental Farm at Khandesh, we observe that Mr. Stormont, the Superintendent, recommends that an experiment in cheese-making be set agoing on the farm. The only outlay, he tells us, seeing that they already have cows, would be the purchase of a few buffaloes and goats; whereas if the results were satisfactory the industry would readily be taken up. The suggestion is, we see, strongly supported by

Mr. Robertson, Commissioner, C. D., in his letter submitting Mr. Stormont's report to the local Government. And indeed, Mr. Robertson's support of the proposed experiment must carry no little weight, seeing that he has himself had some practical experience in the matter.

"When Collector of Dharwar," says Mr Robertson, "I had some 8 milch buffaloes, and as I did not require all their milk, I determined to make cheese. I worked under great difficulties, as I knew nothing about it and had no presses or other appliances. I learnt what I could from books, and eventually made some 50 or 60 cheeses of different kinds. Some were, as my friends know, very bad; some, as my friends also know, were excellent,—especially the attempts at Stilton, some of which were equal to good Italian or 'Gorgonzola' cheese. From my experiments, commenced without any practical knowledge and carried out with such appliances as I could make, I was fully convinced that the very best descriptions of cheese could be easily made in India. I beg to support Mr. Stormont's application. If successful he will, I have no doubt, open out a new industry and will enable the cultivator to add to his farm receipts to no inconsiderable extent."

Mr. Robertson tells us he is "*convinced that the very best descriptions of cheese could be easily made in India,*" and, after adding that Mr. Stormont should obtain from England two or three proper presses, the Commissioner goes on :—

"Another point of importance, and regarding which Dr. Lyon might be able to give information, is that cheese to be saleable amongst the natives of this country, should be made with some vegetable rennet. Natives would not touch cheese made with ordinary rennet, and I am convinced that good cheese cannot be made without the use of some rennet. If a good vegetable rennet could be procured, the curd cheeses could be made; they would be cheap and ryots would soon find a ready sale for them."

We are glad to see that the Bombay Government are disposed to encourage the suggestion. "Government," the Resolution tells us, "have no objection to Mr. Stormont's proposed experiments, and an estimate of the cost of the few buffaloes and goats required should be submitted." This request would seem to have been suggested by a clause in Mr. East's letter to the Commissioner, when forwarding the report, in which he expresses a doubt as to the "sufficient importance" of the object in view. But the Collector of Khandesh would justify the expenditure on totally different grounds. He thinks that a few goats and buffaloes might be purchased in order to make the farm complete in the cattle department and with the object of introducing improved breeds of both animals. We ourselves do not think this question of cost deserving of much prominent discussion. It certainly should not be allowed to stand in the way of such an important experiment—if indeed experiment it may be called—as that proposed. Besides, the cost, at highest, cannot be large, and it would be made up for by many corresponding advantages. Stall feeding of the animals, for instance, would have to be practised; but this again would encourage the cultivation of green crops, and thus the available supply of good manure would be largely increased and agriculture generally advanced. Government, however, require to know the cost, and the information will doubtless be forthcoming. After noting acquiescence in the proposed experiment, the Government Resolution proceeds: —"But cheese-making on the English system should not be attempted. In good cheese-making temperature is an essential feature, and it will be well to study the system in use in Italy and similar warm climates, and to procure thence such vats and presses as may be required." This and all other matters of secondary importance will doubtless meet with due consideration when once the cost of the animals has been sanctioned. We hope this will be accorded without delay, so that no time may be lost. The cheese-making industry has within the last few years taken gigantic strides in America, and we see no reason whatever why something should not be done in this country.

The *Madras Athenæum* notices a short paragraph in our last issue on paper-making from sugar-cane fibre, and in doing so in a kindly spirit, we fancy he has missed the point of our remarks. We did not recommend the scheme, as, on the data we had at our command, it would have been folly to have done so. We simply suggested the advisability of looking into the question. Our contemporary says we have ignored the cost of machinery; by no means—only we did not take that into account as a special charge in connection with paper-making from sugarcane fibre, because, let the fibre or raw material be what it may, machinery will be needed, and we do not imagine that in the case of the cane fibre the machinery will be specially expensive. Should the fibre from sugarcane make good paper, the great advantage is that the raw material, being at present almost a waste product, will practically cost nothing. Hence, other things being equal, paper from this fibre ought to be a profitable industry for India. We have the raw material at hand, the only cost of which would be the difference in price between it and the substitute which the farmer would have to purchase for his cattle, the sugarcane waste being at present utilized as cattle food. We are pleased to have the subject alluded to by our contemporary, and see in the article another illustration of the fact that however "benighted" the Madras Presidency may be generally considered, it has always taken an intelligent and active interest in such subjects as have for their object the amelioration or improvement of the condition of that unfortunate but indispensable factor in Indian economic politics,—the ryot.

Our contemporary has also a few pregnant remarks on an even more important matter—that of the re-afforestation of India—and promises to return to the subject at an early date. We question if any subject exceeds this in interest both to the Indian cultivator and to the statesman. It affects the one as much as the other, and in a country like this, where agriculture may be said to be the sole occupation of the people, and where so much depends on the rainfall, anything bearing on this latter must have an absorbing interest.

The total amount of printing paper imported into India last year, was 52,263 cwt. valued at Rs. 12,57,528. Bengal received 31,857 cwt., and Madras but 3,776 cwt. The value of the writing paper and envelopes imported was over fourteen lakhs. Other kinds of paper were received to the value of Rs. 4,99,214. Thus, India pays Europe, chiefly England, over thirty lakhs of rupees annually for her paper. Is there no enterprising individual to start a paper mill, for turning out texture equal to what is imported? With the raw material to manufacture from at our doors, it seems a disgrace to the energy and speculative spirit of this country that she cannot compete with a costly industry that has to import its wares across the ocean. We know the experiment has been partly tried in India, but we do not think it has had a fair trial, and we believe great things may be expected from a paper industry in this country when once it is properly established.

A Company in Florida, according to a contemporary, has been for some time past, making paper from the palmetto leaf; and so great has been its success, that measures are being taken for the establishment of twenty other paper mills in such places as the palmetto leaf may be found in sufficient abundance. "Are we to wait, as in some other cases, until our friends the Yankees come and show us how all this is to be done," he asks. Perhaps so. Material is abundant in India, but we lack the necessary skill and capital.

Part IV. of the present volume of the "Records of the Geological Survey of India" has been published, and contains much matter of interest including, among others, two articles entitled "Note on Reh or Alkali Soils and Saline Well waters", and "The Reh Soils of Upper India," respectively written by W. Center, M.B., Chemical Examiner, Punjab Government, and H. B. Medlicott, M.A., of the Geological Survey. A correspondent, having seen the notice of Dr. Center's paper which we quoted in our October issue, recently wrote to us requesting us to publish the paper itself when it appeared in print. Much as we should like to comply, we regret our inability to find space for the article which extends over twenty pages of the "Records."

Attention has of late been called to the steady increase in the growth of opium in Persia, and from a Mozambique correspondent of the *Times of India* we now learn something as to the prospects of the opium-producing fields of Eastern Africa. As compared with Indian opium, both the Persian and African opiums are virtually untaxed, and in spite of their inferior quality, which may probably be improved, this freedom from export duty gives them a great advantage with the Chinese customers. It is not difficult to imagine a time when they may seriously affect the most important branch of the Indian revenue. In Persia the new industry has taken firm hold, in Mozambique it is still something of an experiment. The Mozambique Opium Company was formed in Lisbon three years ago with a capital of £100,000 sterling. The Portuguese have granted the directors 20,000 acres of picked land at a nominal rent, and given them the exclusive right of cultivating opium in Mozambique for ten years free of

any tax, and thereafter for a further twenty years on the payment of a duty of £5 per chest only. Judging by the letter of the inspecting engineer, which we publish elsewhere, the land and the water-supply seem all that could be desired, and the present crop seems to be quite up to an Indian standard. From another letter, written by one of the directors of the company three weeks later than the letter we publish, we learn that the plants had then attained a height of nearly three feet, and had commenced to yield opium. Five and one-third beegahs had yielded 170lbs of opium, equal to the rate of 32lbs per beegah.

ATTEMPTS have at various times been made to introduce the cultivation of Carolina paddy into parts of India, without, however, much regard to whether the climate of the locality where the experiment was tried, was suitable to this particular kind of rice or not. Some success, however, appears to have been met with in its cultivation in the lower portions of Ceylon, where, after sundry failures, the proper season for sowing and the proper methods of its cultivation being ascertained, its growth has rapidly spread, so that now over 6,000 bushels are annually sown. The yield is stated to be one-third greater than that of the ordinary qualities. The kind experimented upon is the golden variety ; and though the acclimatized grain has lost its dark golden colour, it has not deteriorated in size or weight from the seed first introduced. It ripens in four months and fetches a higher price than other kinds. Carolina paddy, however, requires very careful cultivation, and the cultivation of indigenous varieties of the best kinds on the ridge-system (as is the custom with Carolina rice). is likely to be more successful than experiments with foreign varieties requiring particular conditions of climate. The experiment is to be carried on in Madras, and especially at the Saidapat Farm, and elaborate instructions have been issued by the Madras Government for reporting the results.

OUR Australian contemporary, *The Leader*, in its special report of the opening of the exhibition at Melbourne, gives an account of the Indian court, from which we extract the following as being of interest to our readers :—

The representation of the raw products of the empire is on an extensive scale, and are for the best part made up of samples of cotton, jute, fibres, silk, indigo, lac spices, drugs, dyes, tannery materials, tobacco, cigars, coffee, and tea ; of this last product there is an especially good show. Tea forms at the present time one of the chief exports of the empire, and is carried on almost exclusively by English planters. The samples are numerous and a gentleman (Mr. Sibthorpe), who is one of the Commissioners, has been specially delegated to this branch by the Tea Syndicate of India. To enable visitors to form a fair judgment of the value of Indian tea, it has been decided to hold tea parties in a *Thain* or chapel attached to a pagoda, which has been erected by the Indian commissioners alongside of the Ceylon court. The *Thain* itself is an attractive feature of the court, and is built of wood carved in the most extravagant fashion by Burmese workmen.

WE have received the Report of the Botanical Gardens, Saharanpur, for the year 1879-80. The work of both those and the Lucknow Horticultural Gardens are much the same, *viz.*, raising trees (ornamental and useful), flowers, and vegetables for distribution, and conducting experiments in acclimatizing staples which are likely to prove useful in Northern India. We extract the following remarks on the Report from the columns of an up-country contemporary :—

Amongst others the sweet chestnut and the olive appear to promise the greatest success. Mr. Gollan (the gardener) and Mr. Ridley (of the Lucknow Gardens) are not quite of one mind as to the merits of acclimatized vegetable seeds. As some kinds, however, such as artichokes, beans, peas, and cauliflowers, are admitted to succeed at Saharanpur as well as at Lucknow, there is not so very wide a difference of opinion as would appear at first sight. The carrot and *prosopis* trees are grown at Saharanpur to a considerable extent but do not promise to take the place of any existing fodder trees in India. The *euch'ena luxurianas* or *reana* is definitely ascertained to be only fit for garden cultivation. *Rhea*, too, on which much time and money has been wasted, is found to be quite unsuited for the N.-W.P. Of cottons the Bamiah gave the finest staple, but its cultivation is highly expensive, and the plant requires far greater care than the ordinary cultivator can be expected to bestow on it. The New Orleans and the Upper Georgian promise to be very successful. There is, however, always the danger lest imported cottons should degenerate sooner or later, as the Hinganghat undoubtedly does in the N.-W.P. and the American has in Dharwar. Thousands of mulberries were planted out for the extension of sericulture : and it was found that the *Morus multicaulis* was the earliest to give a good crop of leaves, the *M. chinensis* giving a later though a richer and more nutritive crop. The *Catalpa bignonioides* promises to be a most useful tree, the hardness of its wood makes it invaluable for railway sleepers. It is also light, and takes a brilliant polish. The Saharanpur gardens supply several drugs to the Medical Department from either Saharanpur, or one of the hill gardens at Mussoorie or Chajuri. Mr. Duthie, however, proposes to change the site of the Mussoorie gardens, which are badly situated as regards light and water, and the area of which is very limited. Excellent sites could be obtained amongst the hills of Jamisar Bawar, with a far superior climate to that of Mussoorie. The museum has been enriched with many valuable additions notably the magnificent collection of the Kurrum Valley *flora* presented by Dr. Aitchison.

The Institution seems to have done good work and has the advantage of superintendence by a scientific botanist, Mr. Duthie, assisted by a thoroughly trained gardener, Mr. Gollan. Under these conditions the report is of more than local interest ; for indeed the Saharanpur Gardens are in correspondence with all the principal Botanical institutions of the world.

IT is satisfactory to learn from the Review of the Maritime Trade of British India with other countries, for the official year 1879-80, recently published, that the import and export trade had very largely recovered from the depression of the previous year as regards merchandise. With reference to treasure, the re-appearance of the normal figures of small exports (as compared with the exports of the three previous years), and large net imports of gold, indicates a return to prosperity, and an increased demand by the people of India for the precious metal, to be hoarded and converted into ornaments. The trade with the *United Kingdom* is, as might be expected, by far the largest item of Indian Maritime commerce, and constituted, for the year under review, 53·8 per cent. of the entire trade. As compared with that of 1878-79, there was an increase of over 447 lakhs. With regard to the European continental countries, the imports into India are of very small dimensions when compared with the exports. From *Austria* the imports are chiefly paper, glassware, beads, and apparel, the total value being about 11½ lakhs; while the exports chiefly were cotton, indigo, and hides, amounting to 186 lakhs. From *France* the imports are, millinery, clocks and watches, brandy and wines, and silk stuffs, value about 43 lakhs; the exports to that country being coffee to the value of 4 1 lakhs, cotton 169 lakhs, indigo in small quantities, seeds valued at 101 lakhs, raw silk and shawls, the last item showing a marked decrease from former years. The total value of exports to France amounted to 484½ lakhs. Imports from *Germany*, of coals, spirits, and salt, amounted only to 6½ lakhs, and the exports about 27½ lakhs. With *Holland* the trade is nominal, India importing about one- and- a-half lakhs' worth of gin and curacao, and exporting cotton, rice, and linseed to the value of 21½ lakhs. To *Italy*, India sent 145 lakhs' worth of cotton, hides, seeds, raw silk, and tobacco, a trade in the latter article being now fostered—the total exports being valued at 220 lakhs, the imports, being chiefly coral about 4½ lakhs, and hops 1½ lakh. These, however, are South German hops imported from Venice, and appear to be superseding English hops in Indian breweries. For the last four years no ship has brought anything to India from a *Russian* port, and our exports were confined to gum and cotton, to the value of Rs. 78,000. The trade with other European countries is not worth mention.

THE Administration Report of the Baroda State for 1878-79 shows that under the Minister, Rajah Sir T. Madava Rao, K.C.S.I., and under the Agent for the Governer-General, P. S. Melvill, Esq., C.S.I., the State is becoming, in all departments of the administration, a model one. As regards the progress made in agricultural affairs, we learn that—

Waste lands were brought under cultivation during the year at an assessment of Rs. 60,000. With reference to the unfavourableness of the seasons, the fall of rain was generally double, and in some places greatly more than double that of an average year. But the rain came all at one time, or in other words, it was badly distributed and the consequence was that all the *kharif* crops, except rice, suffered enormously. The staple food of the people is *bajri* and *jowari*, and to these the excessive wet was very injurious. Locusts and grubs did much injury. The *rabi*, a cold weather crop, was good. In Baroda however, the *rabi* is an insignificant harvest generally as compared with the *kharif*. Prices continued about twice as high as in an ordinary year. *Bajri* sold during the year at an average rate of 15½ lbs. per Baroda rupee, and rice at 13lbs.

THE *Madras Times* recently asked whether anyone had attempted the cultivation of hops in India, and in reply we see that "Hops" writes :—

"Referring to your inquiry in your issue of the 15th instant as to whether any one has tried to grow hops in India, I may mention that an attempt at its cultivation was, at the suggestion, I believe, of the Managing Proprietor of the Neilgherry Brewery Company, made at the Lawrence Asylum Farm at Lovedale, on the Neilgherries, and from the last annual report of that institution I notice that it proved a failure. Hops I read in the *Brewers' Guardian* "will thrive on any land where one can grow wheat or corn ; but it prefers a deep soil—the deeper the better ;" and also that "skill and care" are indispensable

in its culture. Perhaps the Farm Bailiff at the Lawrence Asylum might be able to afford us full information in regard to the cause or causes which resulted in a failure. The successful culture of hops on the Neilgherry hills would, in every way, prove very advantageous. The Neilgherry Brewery Company import all hops used in the manufacture of their ales—which are obtaining a wide reputation, and, when last at Ooty, I saw some excellent varieties of English, Bavarian, and American hops in their stores. We would hail with delight the day this company will be able to brew its ales from hops grown on the Blue hills. Hops, I hear, have been successfully grown in Northern India, and with a little care in regard to soil, locality, preparation of the ground, &c., its successful culture on the Neilgherries could be secured."

Hop cultivation has made considerable progress in parts of India within the last few years and there are those who think that the time is by no means distant when the industry will assume an important position in Inda's staple productions. Some interesting information and data on this subject will be found in another column.

A LETTER addressed to the *Ceylon Observer* by Mr. J. Holloway, a planter of that colony, furnishes some curious particulars as to the profit derivable from the cultivation of the croton-oil tree. The information is brief, but calculated to provoke futher inquiry where the subject finds interest :—

Even taking the seed at 6*d*. per lb., 20lbs from each tree in one year (trees can be grown among coffee 15 feet apart without injuring the coffee) and say 190 trees to the acre would be Rs 950 per annum from one acre of croton trees after the fourth year, besides what income there may be from coffee or other produce.

The croton is evidently a quick growing tree, coming as it does to maturity in about four years and throwing out by that time a considerable amount of shade. This we should imagine a suitable tree for planting on land that has been too ruthlessly deprived of its clothing.

THE *Rangoon Gazette*, says there is " a great scarcity of food in Java, almost amounting to a famine, hence the steady demand for rice from this port for the Straits whence it is sent to Java." Large shipments have been made, including many thousand bags of Bengal rice brought over to Rangoon from Calcutta. Our contemporary adds :—" It is likely that the demand will continue, and, as there is still a fair quantity of paddy in stock, milling will go on till the new crop comes into the market." A later issue of the same paper informs us that crop prospects are said to be rather unfavorable in the Bassein and Henzadah districts, owing to the rains not being copious when they were wanted. The crops in other parts of the province are however likely to turn out well. The demand in Rangoon for grain for Java continues. In the fortnight ending 8th instant, about 40,000 cwt of rice were shipped to Penang and Singapore *en route* to Java. Our own correspondent at Rangoon tells us that although complaints come, more especially from Akyab and Thayetmyo, that the paddy crop will suffer from the scarcity of rain towards the end of the monsoon, yet taking the whole country it is thought the crop will be an average one. The outturn last season was exceptionally good.

A FIREPROOF composition seems at last to have been discovered. In the report published by the *Journal of Applied Sciences* of the Exhibition in Paris, last year, mention was made of some muslin curtains exhibited by M. A. J. Martin to which flame was applied, again and again, without consuming them. The composition M. Martin employs for rendering paper, wood, and textile fabric, impervious to fire, is the following :—

	Parts.
Pure sulphate of ammonia	80
Carbonate of ammonia	25
Boracic acid	30
Pure borax	17
Starch	20
Distilled water	1,000

The materials are dipped in this solution while hot, so as to be thoroughly impregnated ; when they are dry enough, they are to be ironed in the same way as ordinary starched fabrics.

IN a home paper we read that a gentleman in San Francisco having in his conservatory various hard-wooded and thick-leaved plants covered with insects, tried, with only temporary success, the tedious and expensive plan of washing with soft soap ; also syringing with various substances, including carbolic acid which injured the tender growths. He then hit upon what proved to be a very effectual remedy, of which he says :—

"I procured from a druggist an atomiser, and, filling the bottom with kerosine, sprayed over a camellia to be experimented upon. It was a very dirty plant, the branches and leaves of which were covered not only with scale but with black fungus ; a very small quantity sufficed to vaporise and cover the entire plant. After the fluid had evaporated and the plant was dry, the scales were found dead, shrivelled, and partly detached, and with the slightest touch fell off ; the black fungus, also which, everybody knows is so tenacious on the leaf, was dried up into a loose powder, which a shake sent to the ground.

"I did not confine myself to the single experiment, but have since used kerosine in the spray on several other plants pestered and diseased with these parasites, orange trees, &c. I have also tried atomised kerosine to destroy aphis on pelargoniums and on the soft and tender flower-buds of greenhouse roses. I destroyed the aphis, but the new and tender growth of my plants was destroyed also."

AN American paper states that under the name of "Ericine," a fine golden-yellow dye is now prepared from the young wood of various poplars, as well as fro m the woody portions of heather, the botanical name of the latter (*Erica vulgaris*) having apparently suggested that of the dye. Young branches and shoots of poplar are cut off, crushed and brayed, and are then boiled in alum-water, the proportions allowed being 10 pounds of wood and 1 pound of powdered alum to each 3 gallons of water. The liquor is boiled from about twenty minutes to half an hour, and then filtered. In cooling it thickens and clears, throwing down a greenish-yellow deposit of resinous matter. When sufficiently clear, the liquor is again filtered, and then left exposed to the air for three or four days or more, according to the weather and the state of the atmosphere. It quickly oxidises under the action of the light and air, and assumes a rich golden tint. In this state it can be used for dyeing fabrics of all descriptions. For yellow and orange-yellow shades, it is used alone; mixed with Prussian blue, it gives green; with oak bark, brown and tan; with cochineal, &c., orange and scarlet shades. Or the colouring matter can be precipitated, and then makes a fine and perfectly innocuous yellow body-colour for wall-hangings and such like purposes.

THE fruit of the " shrubby trefoil" (*Ptelea trifoliata*) is bitter, and in odour is almost exactly the same as the hop. In fact, the fruit is sometimes used in America as a substitute for the latter ; and for this reason the plant is also known as the " hop-tree." In consequence of the ravages of the *phylloxera*, the French are now looking about for new beverages, and, as observed in the *Revue Horticole*, if the destruction of the vine continues, there is no doubt that wine must be largely replaced by beer. M. Charles Baltet has discovered that the fruit of the " shrubby trefoil" makes as good beer as hops. At a recent agricultural exhibition at Chalons-sur-Marne a M. Ponsard exhibited a sample of beer in which the fruits of this plant were substituted for hops, and its quality and flavour are reported as being equal to those of the best Strasbourg beer. Surely this plant would grow on the Nilgiris and in other parts of India if carefully cultivated.

VARIOUS experts have given very different estimates of the recent wheat harvest in England, and as the truth is of some importance to India as a wheat-exporting country, it is disappointing to find one calculation appraise the crop as one considerably over the average, whilst another gives it as at the best 15 per cent below the average of the century. The fact is that even experts have been misled by the miserably poor crop of 1879, and that each authority has been impressed with the conditions of those countries with which he is most familiar. That the wheat crop of the west, south-west, and north-east of England is fully up to the average, there appears no question, but that average is greatly reduced by the lower outturn of the eastern and south-eastern districts, where, at the outside, 24 bushels to the acre will be threshed. When it is remembered that the average outturn per acre in the United Kingdom is 28 bushels, and that the extreme variation is from 24 to 32 bushels per acre, the effect of a poor crop over so large an area will be fully appreciated. Nor is all the new wheat of good quality; some has been sold at 36*s*. per quarter, a very poor price indeed. It is not, however, so much the outturn of the English harvest, nor even the price at which home-grown wheat sells, that influences the Indian exporter. It is the vast and as yet apparently inexhaustible supplies from Western America which must keep prices low in England, and prohibit exports from India, where Rs. 2 per maund is already becoming stereotyped as a cheap rate. The absence of competition in the American railway system keeps up the price of American wheat still. This is a subject, however, to which we hope to return ; meanwhile India's rival as a wheat exporter is the far west of America.

THE grain-producing capacity of the American States is something enormous. On one day the receipts of Indian corn at the New York Produce Exchange on the 28th ultimo were 908,000 bushels, the largest ever known. The yield for the year is anticipat-

ed to be 13 per cent below that of the previous year. The yield for this year is estimated at 1,345,000,000 bushels, against 1,545,000,000 in 1879. This is Indian corn alone: with other cereals, the produce must be tremendous. Indeed Americans have been known to boast that with a few months' notice they would take a contract to feed the globe. And the production of wheat in the United States, enormous though it has been for many years, is yearly becoming still more immense. Thus, in the course of a single year the outturn of the seven chief corn-growing States—Minessota, Michigan, Ohio, Indiana, Illinois, Lowa, and California—has increased by twenty-five millions of bushels, or from 200 millions in 1878 to 225 millions in 1879. If the harvests of the United States are competing seriously with Indian wheat, they are competing even more seriously with the wheat crops of Russia. It has been calculated that the facility of transport in America places the Russian cultivator at a disadvantage of nearly five shillings per quarter.

THE Samarang *Vaderland* contains the following description of a vegetable tallow found in Siak greatly resembling the well-known *minyak tangkawang*.

"Sometime ago the attention of the Government was directed to a certain fatty substance termed *minyak suntei*, which is prepared in very large quantities in the kingdom of Siak from the fruit of the *suntei* tree. On inquiry it turned out that the *suntei* tree is similar to the *tangkawang* tree, which in the Western division of Borneo yields the *minyak tangkawang*—a fatty substance which is often used there in dressing food instead of butter, and which is extensively exported to Singapore. Both these fatty subtances appear to be very suitable for greasing iron and other metals used in the machinery of manufactories and steam ships. With an eye to the low prices of these fatty substances, the Netherlands Government decided upon them for lubricating machinery on board H. N. M's vessels in Netherlands India, instead of the beef fat hitherto used for the purpose. This experiment showed convincingly that *suntei* or *tangkawang* tallow is at least equal to beef fat in quality, whilst the quantity required for ordinary use does not exceed that of the last mentioned fatty substance.

MISCELLANEOUS ITEMS.

THE Annual Exhibition of the Madras Agri-Horticultural Society will be held early in February 1881. A long list of the prizes to be given has been published.

THERE will be an Agricultural Exhibition at Deccan on the 1st January next, under the patronage of Nawab Ashanullah Khan.

WE have received the prospectus of the Maiji Exhibition and Horse Show which will open on the 21st of February 1881. A number of prizes of the aggregate value of Rs. 5,595 will be given for horses and mules and cattle of all kinds. There will also be some prizes for encouraging indigenous art and manufactures.

THE New York Agricultural Bureau's monthly report states that the average condition of the crop of ten Cotton States is more favourable.

THE following articles are exempted from the duties to which they are liable under the Indian Tariff Act, on the ground that they are for the most part re-exported—Gum Arabic, gum Benjamin, gum Olibanum or Frankincense, Mother o'-pearl, and Tortoise-shell.

THE only article of Indian production which now pays export duty, is rice, and the duty thereon realised for the year ending 31st March last, was fifty-nine lakhs.

IN a notification in a recent *Gazette*, it is declared that licenses for the importation of sulphur into British India, intended only for agricultural purposes might, with the sanction of the local Government, be granted without the payment of the fee of Rs. 10, prescribed under Rule 6 of the rules issued under the Arms' Act.

WE read in the *Poona Observer*:—It is reported that "Hoomnee worms" have made their appearance in the Sholapore Collectorate, and that they are destroying the roots of the standing crops. This worm has been described as about an inch and-a-half in length, by half an inch in circumference.

OPIUM is being cultivated with success in Mosambique. The yield is said to be much larger than in India, but nothing appears to be known definitely about the quality.

THE quantity of opium advertised for sale next year is 56,400 chests, in monthly quantities of 4,700 chests. From January to June the number of chests offered for sale will be 2,350 chests of Behar and Benares, respectively.

THE importation of jute to Dundee direct from Calcutta and Chittagong during the nine months ending September, shows a serious decrease when compared with the imports in the corresponding period of last year.

THE indigo season opened on the 9th ultimo with a small sale of about 350 chests, and three more sales have since been held, the total quantity offered by public auction (to 20th instant) amounting to about 1,900 chests; of this quantity, 1,450 chests were sold. The catalogues have, at time of writing, included only about 100 chests of Bengal and Tirhoot indigo, the remainder consisting chiefly of ordinary to middling native Oudes and a few lots only of good and desirable quality.

THE highest price paid as yet this season for indigo has been Rs. 265 per maund for a lot of 47 chests of the mark E. G. W. Banaghat, Chupra.

AMONG the Government "Notifications of Patents," we observe one of Mr. Eugene Charles Schrottky, Agricultural Chemist of Calcutta, for the improvement of indigo manufacture.

MANUFACTURE of gunny-bags is very largely carried on in Cooch Behar and Rajshahye by the people in their own homes and by European mills. In Serajgunge, the jute mills employ some 2,200 people, and are stated to have turned out gunny-cloth sufficient for four-and-a-half millions of bags during the year.

IN Rungpore and Julpigoree, a common home manufacture is that of *sudee* cloth, made from a species of silk derived from a worm which feeds on the castor-oil plant. Cotton carpets are manufactured in large numbers in Rungpore, and exported to other districts, but the manufacture of country cloths is dying out.

FROM a recent Assam Administration Report we see that an important question—of controlling the collection of India-rubber in the Government forests and the trade in foreign rubber imported into Assam—was forwarded to all Deputy Commissioners for report; but as their views regarding this, as well as the other proposals made by the Inspector-General of Forests, were not received before the close of the year, no final steps could be taken for their settlement.

FOOD grains are becoming decidedly cheaper in every district in the Madras Presidency. Last year second sort rice was selling in Ganjam at 13·8 seers of 80 tolahs for the rupee; this year the price is one rupee for 21 seers, or a fall of over fifty per cent.; *cholum* and *ragi* have also fallen greatly in price. In Trichinopoly only 13·5 seers of second sort rice are selling for the rupee; in Madras and South Canara it is selling at twelve measures.

THE *Madras Times* gives the percentage of agriculturists on the total population in the Madras Presidency as 23. The average number of persons dependent on each male agriculturist above 12 years of age as 4·2. The average number of acres cultivated by each male agriculturist above 12 years of age is 4·5. The average payment to Government (including all charges for water) per acre of the revenue-paying area is Rs. 1·4, the average incidence of local rates and cess is 2. The total amount of local rates and cesses paid in land throughout the presidency is Rs. 48,86,953.

A NUMBER of maps of various parts of the Madras Presidency are on sale at the Government Survey Office (Madras). For the benefit of our planter friends, we may mention that maps on the scale of 16 inches to the mile of all the estates in the Nilgiri district, and many of those in the Wynaad and Shevaroy Hills may be had on application. The price is one rupee per 100 acres. Maps of all Coffee Estates, Devarukadus and Wargas, on the scale of 16 inches to a mile, in the Province of Coorg, may be had on application to the Secretary to the Chief Commissioner of Coorg, Bangalore.

WE read in a Bangalore paper that an old soldier there has, after five or six years of patient investigation and persevering effort, invented a new kind of asphalte for which he claims that it will stand the greatest heat of the sun, does not yield or crack under the greatest weight, and will adhere to wood, brick, or stone, in either a horizontal or perpendicular position. The asphalte has been put to a severe trial by the State Railway Engineers at Bangalore, who pronounce very favourably on it. The inventor intends patenting the process, and after that will offer it for sale.

A RECENT examination of the Ceylon pearl banks by Captain Donnan, Master Attendant of Colombo, has resulted in shewing an enormous deposit of healthy mature oysters available for fishing next year. It is estimated that there are now on the banks sixty millions of oysters, which in 1881 should represent a value of Rs. 12,000,000; but it is doubtful if even a half of them can be lifted during the coming season, and the fate of the remainder if left on the banks until the following year, would not be very doubtful.

EXCELLENT cotton is grown in Upper Burmah, and, when high prices obtained, it was shipped to Europe under the name of Pegu. But now it pays better to send it to China and the Shan States, where large quantities are taken yearly by mules, bullocks, ponies, and donkeys.

THE scheme for starting a cotton mill at Shanghai has been revived. A Company has been formed by Chinese, with a capital of Tls. 400,000 in four thousand shares of Tls. 100 each. It is stated that half the shares have been taken up. The Viceroy there is said to approve of the project.

MR. J. J. COLES HARDINGE, the Secretary of the Agri-Horticultural Gardens, Rangoon, intends, we (*Rangoon Gazette*) understand, taking three months' privilege leave and proceeding to Bhamo accompanied by a taxidermist, in order to collect specimens of the *fauna* and *flora* of that part of the country, most of which will, no doubt, go to enrich the collection already to be found at the Phayre Museum and adjoining gardens.

ENDEAVOURS have been made in vain to identify an insect which is very destructive to the sugarcane in South Arcot; but presumably it

is the same as is found in Queensland and British Guiana. The insects multiply in the heaps of refuse and trash left in the plantation, and if these were burnt, as well as the infested canes, the pest would show a marked diminution.

THE oil extracted from cotton seed is said to be largely exported from America to Italy and other countries where olive oil is produced, and thence re-exported as genuine olive oil, which it fully equals for all purposes. A ton of seed is stated to yield 35 gallons of oil and 750lbs of excellent oil-cake. What becomes of the cotton seed accumulated in the process of cleaning Indian cotton?

A NEW wheat pest has been discovered in Ontario. From descriptions received of the insect from different quarters, it is believed that it is the "wheat-stem maggot," *Meromyza Americana* of Fitch. In the mature form this insect is a fly, shaped like the common house fly, but much smaller and rather more slender in proportion to breadth. The *larva* lives in the stem of wheat and destroys the plant by devouring the substance of the stalk. Of course, when the stalk is nearly dissevered, the head of wheat dies off prematurely. The insect will attack oats, barley, or rye, but prefers wheat. The same insect is complained of in New York State.

THE *Melbourne Argus* informs its readers that "the mastication of the betel-leaf (*charica betel*) and nut (*areca catechu*) is a habit which is as common in an Indian community as smoking amongst the English. Both sexes indulge in it, and the great lords and princes who keep large harems have to pay no end of betel-nut money, after the same fashion as our pin-money.

OFFICIAL PAPERS.

PRELIMINARY REPORT ON THE INQUIRY INTO COFFEE LEAF DISEASE.

Dated Peradeniya, the 12th June 1880.

FROM H. Marshall Ward, Esq., B.A., Cantab, Cryptogamist, to the Hon'ble the Colonial Secretary, Colombo.

I HAVE the honour to report that, in accordance with the terms of my engagement, I have been occupied since arriving in Ceylon in February last with observations and experiments upon "coffee leaf disease."

It is proposed to confine this preliminary report to a statement of observed facts, especially as several of these are new; nevertheless, much has been accomplished on the States, in the way of comparing what is already known, and in acquiring further information as to the nature of leaf disease, its distribution and treatment. The true interests of the planters will be, however, best served by a future and more extended report on these matters.

Having made myself acquainted with the literature already published, and obtained as much information as possible on the subject, I at once proceeded to further practical acquaintance with "leaf disease," and commenced a microscopical analysis of the coffee plant in health and disease; this has been continued hitherto in various parts of the coffee districts. Specimens have been obtained from all elevations, and from the most various situations, soils, and climates that the districts afford.

I also placed myself in communication with representative planters, for the purpose of obtaining further information, and made some preliminary experiments with reference to suggestions obtained, in order to test the value of various observations as to the nature of "leaf disease."

On March 15th a tour through the chief districts in the southern and eastern parts of the Central Province was commenced. I made observations on various estates in Hantane, Nilambe, Hewnhetta, Pussellawe, Rambodde, Maturata, Uda Pusselawa, Ambagamuwa, Dikoya, Dimbulla, Badulla, Madulsima, Hewa-eliya, and Haputale.

Two objects were kept in view during these journeys: (1) to gather as much information as possible concerning coffee, its cultivation, its appearance in health and disease, and the experience of planters as to remedial measures; (2) to investigate the pathology of "leaf-disease," and the life-history of *Hemileia vastatrix* under the various conditions afforded by differences of soil, altitude, climate, &c.

During the whole time were kept up as continuously as possible the researches commenced at Peradeniya, and no opportunity was lost in verifying or correcting observations. I carried microscopic and drawing apparatus everywhere, and, as always, carefully figured any objects of importance to the inquiry. A large series of drawings and notes was thus accumulated for future guidance as new lines of research are opened up.

On my return, experiments were at once commenced to determine certain points suggested by the experience gained. These are still proceeding and yielding results. Meanwhile it is my duty to bring some examples forward, as illustrating and warranting the conclusions so far arrived at.

(1.) Several beds of Jamaica coffee seedlings in the Peradeniya gardens appeared quite healthy on 10th February 1880; each seedling was about eight inches high and bore six or eight pairs of leaves. Specimens were selected and microscopically examined; nothing shewed that the internal structure was abnormal, or that they were functionally wanting in any way.

Twenty-four of these seedlings were potted off in baked earth and removed for future experiments. To windward of the beds, and separated from them by an ordinary gravel path, were several old coffee trees, eight to ten feet high and badly diseased. The open verandah, in which the selected plants had been placed, also lay to the leeward of a quantity of old and diseased trees, separated by many yards of garden.

During each day following, the leaves of specimens from both beds and pots were examined; on the lowermost leaves were found a few scattered and ill-defined spores and tubes evidently of fungoid nature, as well as delicate threads of spiders' web, particles of sand, &c. The uppermost leaves shewed no such growths.

On the 20th February, the first yellow patch was observed on the lower side of a lowermost leaf of one of the exposed plants: during successive days several more patches appeared, always on the older or lower leaves, and in a month all the beds contained badly diseased specimens. By this time also the selected specimens had become diseased, chiefly on the "seed-leaves" (cotyledons).

The most careful examination failed to shew the diseased spots on any other part of the seedling than these older leaves; and even in the leaf stalk no fungus or other abnormal structure was observable, and to all appearance the root and stem were in perfect health.

(2.) Specimens of disease patches in all stages were selected from the above plants. Some were very small, hardly yellow "pin-spots," only seen when held up to the light; others older, larger, and more oily-looking; still older ones were covered below with yellow or orange "rust;" while yet further advanced irregular patches presented brown or black blotches in the central part, the yellow powder being at the edges.

The microscope establishes the following facts, and I have confirmed the observations since by examination of specimens from all parts of the coffee districts at various elevations and seasons.

Thin slices of the "pin-spots" and pale yellow patches, taken in all directions and examined fresh, or treated with chemical reagents shew that this part of the leaf has the passages between its cells which lead to the exterior blocked up with a much-branched, tubular, coral-like mycelium: the short stumpy branches applying themselves here and there in their course to the outside walls of the cells. The contents of the tubes are very granular and oily, usually coloured by a pigment varying from yellow to deep orange-red.

The older patches present similar features exaggerated, but the branched tubes of the mycelium have sent peculiar groups of the processes outwards through the outlets (stomata) of the epidermis: on reaching the exterior, the ends of these branches form swellings which soon become filled with deep orange coloured pigment and granules, and the groups of bodies seen from above present the appearance of rosettes. Since these bodies are easily rubbed off, they form a powdery mass on the outside—the so-called "rust."

Similar examination of the brown or black central blotches shews that the leaf cells have lost most of their contents, turned brown, and collapsed: thus the upper and lower surfaces come closer together, and such parts are thinner than the rest of the leaf. Usually, a number of black dots are seen on the upper and lower surfaces.

There can be no doubt that the tubular branched mycelium has been feeding upon the contents of the leaf cells, turning the green colouring matter and other substances into the granular and oily masses found within it and finally passing forth into the bodies forming the "rust" powder; and when we reflect upon the immense quantities of matter thus derived and thrown off from the leaves, we may understand in some measure the terrible effect produced upon the coffee plant.

(3.) Some of the yellow "rust" was placed in water on a glass slide and examined under the microscope. Each "grain" of the powder is a hollow case somewhat kidney-shaped in longitudinal section, and triangular, with one angle downwards, in transverse section: it is narrower at the end attached to the mycelium. The upper curved side is studded with papillæ, or wart-like projections of its outer colourless coat: the two smooth sides converge below to a rounded longitudinal ridge. Such a figure exhibits various forms if projected in different positions. As said, this papillate body has granular orange-coloured contents.

Many of them soon swell in water, and become filled with globules of clear fluid (vacuoles) from the equal and rapid imbibition of water; the papillate body now appears as if filled with spherical clearer bodies embedded in the colored mass. These globules are not always equal in size, but generally are nearly so, and average $\frac{1}{10}$ to $\frac{1}{8}$ the diameter of the whole mass: not only by their appearance, refusal to absorb staining reagents, and general behaviour, but by the fact that they can be made to disappear and re-appear, am I convinced of their fluid nature.

Others of the papillate bodies, however, do not fill with globules; but swell and soon loose their reddish colour, and the contents become very granular and grey-looking. After a time, varying from a few hours to a much longer period, the granules, which are very minute and numerous, pass into a state of violent motion to and fro in the fluid contents of the papillate body. This motion is too active to be merely physical, and has been observed too often to be accidental. After remaining in this state for some hours, the granules pass out into the surrounding water, and become widely distributed, leaving the empty papillate case behind: their ultimate fate is not yet satisfactorily established.

A piece of leaf, with "rust" on it, was exposed to sunlight, and found to become paler. Examination shewed that the majority of the papillate bodies had lost their contents, and remained as empty, colourless cases: the further history of the contents has not been yet ascertained.

On 22nd February, during an observation on the moist papillate bodies, several of them were found to have emitted tubular processes from one to

four points of the circumference; these tubes are continuations of the inner coat, and the coloured contents pass into them. Further observations have shewn that one tube usually grows to a great length, its cavity is continuous, and no partitions form across it, it takes a curved and even coiled course, and sends out many short branches at frequent intervals: the diameter of the tube is about one-fifth the breadth of the papillate body. A streaming of the contents is often seen, and the coloured matter passes gradually into the ends of the branches. From the above facts it is inferred that the papillate bodies are *spores*, which in certain circumstances germinate and produce a tubular mycelium: further facts are mentioned hereafter.

The minute black dots on the dark parts of old patches are found to contain multitudes of very small hyaline spores, budded off from the ends of delicate filaments which are matted together into a hollow case beneath the epidermis: the cavity becomes filled with the spores. These facts are here mentioned because the black points are so universal; they are not yet known to have anything in common with the above phenomena beyond what has been now stated.

(4.) On 22nd March the peculiar appearance presented by certain patches of "rust" obtained from "Inverness" estate was shewn to be due to a different kind of body from the papillate spores. The "rust" spots appeared pink, rather than orange-coloured, and were of a pasty rather than powdery character. Among the clusters of papillate spores the microscope shewed certain bodies of little more than half the size, quite smooth, crowded with red granular matter, and of a shape somewhat like a turnip or peg-top: each was on a narrow stalk, and many had a central boss on the top. These are not to be confounded with immature papillate spores.

Associated with the same external features, I have since re-discovered these bodies at various places and times, *e. g.*, Maturata (March 25th,) Ambagamuwa (April 5th), Peradeniya (May and June), and extended observations have elicited the following information.

From the top, opposite the stalked end, a stiff tubular prolongation of the turnip-shaped body is sent up: the coloured contents pass in, and when it has reached a length equal to six or eight times that of the original body, four partitions have cut the tube into as may chambers. From each chamber a delicate lateral branch is sent forth, which at once buds off a small globule at its tip: this globule receives the coloured contents, falls off, and persists, while the rest dries Here, again, I think we are justified in concluding that the turnip-shaped body is a spore that on germination produces a short tubular septate mycelium, whence small spores of another kind (*conidia*) are budded off; such cases of different kinds of reproductive bodies are well known to all mycologists.

The small globular spores have been made to germinate, but died at an early stage in all cases from the attacks of introduced organisms (*Bacteria Torulae*), &c., which are so troublesome in these experiments.

(5). The question what becomes of the long and curled tubes emitted by the papillate spores has been followed up with more success lately. The following facts have been obtained by growing the spores on the under side of thin glass squares, so arranged as to form the roof of a small cell kept moist by wet blotting paper; various contrivances to avoid the introduction of foreign fungi need not here be detailed.

Having attained a considerable length, all the colouring matter, &c., passes along a branch, and a pear-shaped swelling is formed at its end; this receives all the contents, a septum forms for the first time, and we have a swollen reddish body separated off from the empty tube and spore, which shortly die off.

This coloured body has been seen to send out branches. A number of rather large hyaline motile bodies (zoospores) generally make their appearance, and two of these have been seen to fuse. The connection between these various facts demands further inquiry.

(6.) Besides numerous examinations in Peradeniya no opportunity was lost during my journeys to study the vegetable forms which appear on the exterior of coffee; in all I have drawings of about a dozen different kinds of spore or of filamentous growths common on the leaves. Of these several are obviously blown by the wind on to the leaves; some germinate freely, while others do not appear to do so, while one or two have been traced to common forms abundant everywhere.

It is not proposed to describe here the various spores met with. Obviously while it will be necessary to trace the origin and destination of each form until we are either sure it is foreign or is connected with "leaf disease," the kind of inquiry thus instituted presents no ordinary difficulties: until we are quite satisfied as to which of the filaments, if any, belongs to *Hemeleia*, we are in the dark respecting one phase of its life-history, and until we know the whole of its life history, remedial measures are premature.

(7.) Numerous attempts to directly infect coffee plants with "leaf disease" have as yet failed. I may select the following from a multitude of examples as to methods adopted:

1.—Papillate spores were sown on the under side of a young leaf, covered with a glass cell, and placed in various positions, temperatures, and dry or moist atmospheres.

2.—Similar sowings were made on thin slices of coffee leaf, kept moist in glass cells—some in water, other in various solutions.

3.—Sections of disease-spots were treated as above to try and induce the mycelium to spread from the leaf passages either on to other slices or on to the coffee leaf.

4—Several of the spores found on the coffee-leaf have been sown as above. The chief cause of failure here has been the unavoidable introduction of other forms which increase so rapidly as to destroy the selected ones before their normal fate has become indicated.

In drawing any conclusions from these experiments, too much stress cannot be laid upon the fact that, however carefully we plan an experiment in the laboratory, we fall short of Nature's conditions; further it must be admitted that until the fate of the various forms found on coffee is ascertained, we may have missed a phase in the life history of *Hemileia*. I am therefore pursuing closely the different changes passed through by these spores and their products, and hope to place the results before you in a future report.

In conclusion, I feel justified in drawing these inferences from what has been seen so far. Derived from some source purely external, a fungoid organism finds its way into the passages between the cells of the leaf: here it has a term of existence shewn to the observer by the origin and spread of the yellow "disease spots", caused by the changes in consistence and colour of the leaf contents at those places.

The outbreak of the yellow "rust" from the leaf passages, through the stomata takes place when the leaf begins to fail in supplying sap. Such an explanation is in accordance with all the facts yet known to me, and with the present state of physiology. In seedlings, the cotyledons especially becomes yellow, and in older plants the lower leaves usually suffer first: on wind-blow ridges, quartz patches and dry soil generally, bad attacks of rust are conspicuous when more sheltered and moist portions of the estate do not appear to be suffering: in sudden dry weather "an attack" commonly comes over an estate, while during the last stages of crop "leaf disease" is often very bad.

Now, if the mycelium, ramifying among the loose cells of the leaf, is absorbing its food from those cells, as is well known to be the habit of such parasites, we can see how so much more work is thrown upon the plant. Whereas a leaf normally supplies a certain quantity of elaborated food for the tree in a given time, we have here the same leaf compelled to provide food for tree *and fungus*—its cells must work the harder and its life be the shorter.

Until we fail to account for the ravages of leaf disease according to known principles, we have no right to seek an explanation elsewhere. Many and in some cases elaborate experiments are being planned to establish the important point as to what actually occurs between the fall of the leaf, with its "rust" and mycelium, and the re-appearance of the yellow "pin-spots." I have already indicated the direction in which these are leading, and it only remains to patiently carry on research. When it is remembered that these germinating spores have to be kept under observation during the night as well as day, that all kinds of minute organisms have to be guarded against, and hence that out of many attempts few succeed, I hope that the importance of this plan will be admitted.

In conclusion, I must beg to be allowed to thank the planters and other gentlemen who have so kindly and efficiently aided me thus far in what has become to me a labour of love.

ANALYSES OF QUARTZ.

FROM R. Smith, Esq., Assistant Metallurgist, Royal School of Mines, to the Under-Secretary of State for India, India Office, London, S. W., dated Jermyn-street, London, 12th May 1880.

I HAVE the honor to inform you that the 24 samples of quartz and pyrites, obtained by Mr. R. Brough Smyth from the reefs near Devala in the South-Eastern Wynaad, India, and marked as under, have been submitted to examination, with the following results :—

No. 1.—"Hamlin's Reef."—
Gold—0 oz. 2 dwts. 23 grs per ton of 2,240lbs.

The whole of each parcel of ore was reduced to a very fine powder to obtain a fair average sample before submitting it to examination.

The above are the mean results obtained from two or more assays of each sample.

The numbers from 15 to 25 do not correspond with those in the printed list of Mr. R. Brough Smyth, forwarded with the parcels of ore; the numbers marked O are therefore inserted for convenience of reference.

The silver present is for the most part alloyed with gold as "native gold" and would be extracted with it. A portion of the silver and also of the gold is probably present in the pyrites or other associated minerals.

The copper is present in very small quantity in several of the samples, but in much less proportion than was formed in No. 16 (Bear Reef).

If any difficulty is experienced in the extraction of the "native gold" from No. 16 by the process of amalgamation, it might prove desirable to concentrate the "native gold" with the pyrites by a "dressing" or "smelting" operation according to local facilities, for subsequent treatment for the separation of the copper, silver, and gold. I did not notice any free "native gold" in any of the samples of ore.

SELECTIONS.

HOP CULTIVATION.

Hop cultivation in certain districts in India has made most satisfactory progress within the last few years, and some growers, perhaps it would be more correct to say, experimenters, are sanguine that the time is by no means distant when, eventually at any rate, this industry will form one of the many important staples of our Indian productions, and render the importation of hops, now by no means an unimportant factor in Indian imports, almost, if not wholly, needless. That is, with persevering care, close application, and prudent patience, India my reasonably hope to become, in this matter of hop culture, independent of the home trade, every day developing, necessarily, greater proportions. It may not be altogether without interest, to hop cultivators in India, to mark some few details in connection with the area, yield, value, &c., of the hop cultivations in Great Britain.

Some idea may be formed, even by the most unobservant, of the extent to which this industry is prosecuted in England from the area it occupies in different counties. Thus in Kent, the most extensive garden of all, there are 43,400 acres under cultivation: Sussex claims a hop-growing area of 9,974 acres: Worcester district, or county, 2,609, and Hereford counts 5,947 acres under hop cultivation. In the county of Surrey there are only 2,376 acres, but it is said to be equal to any hop land in the world: while in the adjoining county, Hampshire, the area is given as 3,094 acres. Altogether, England may be said to have, under hop cultivation, 67,400 acres, growing in favorable season an average of, say, eight cwt. per acre or rather more than half a million cwts. in all, at a money valuation approaching three millions sterling.

But hop cultivation, even in England, and under the most favorable conditions, does not appear to be an unmixed blessing to those immediately concerned in it. People who ought to know, aver that no branch of agriculture is nearly so costly. The original outlay in forming a garden may be estimated according to attendant circumstances, at from £70 to £100 per acre The plants demand incessant attention, the most watchful care. They must be thoroughly weeded and fully ploughed out between the drills; they must be tied up to the poles at intervals while shooting; and when the flowers will repay the picking, that is, we suppose, when in a sufficiently healthy state of forwardness, gangs of hands must be employed to gather them. And as no cultivation is more expensive, so no crop is, it is said, more exhausting, and the ground being never allowed a rest, the consumption of manure is something enormous. Then again the grower can never be absolutely easy in his mind till the hops have been picked and passed through his kilns, for no crop, anywhere, is believed to be more uncertain. Before 1863, when matters had gone fairly well, and the anxious grower, might reasonably congratulate himself on a satisfactory gathering, his anxieties were so far at an end. Prices might, of course, vary, but the steady home demand might be relied on to absorb or dispose of the year's crop. Even then, a generally good season was far from constituting an unalloyed benefit. When every man's neighbour happened to be as well off as himself, there was inevitably a serious fall in prices, while the outgoings were above the average, the pickers being paid by quantity. Now, what the home grower hoped and prayed for was, that the hops on his farm might happen to be luxuriant, while they were shrivelled everywhere else (according to the philosophy which credited human nature with some satisfaction in the misfortune of its friends) and then his prime samples of 'whitebines' or 'goldings' fetched almost fabulous prices. We are told that well authenticated traditions still linger in the hop counties of gardens in favoured localities that were mines of gold so to speak, to their owners. But all this was altered in 1863, the year referred to, when the duty on foreign hops was abolished (something akin to the more recent cotton duties abolition): ever since the hop grower has had to bear the losses of bad years, without the consolation of feeling that as before, they might be amply made up to him in some extraordinary season; or possibly without the comfort of knowing that some of his neighbours were worse off than himself.

Previous to the repeal of the duty, though the imports appear to have been, for the most part, insignificant, no doubt they were, occasionally considerable. For, though the hop is a native of English hedgerows, the English climate is rather too damp, perhaps too cold, for its nurture; and continental growers are almost independent of the weather that so frequently proves disastrous to the British farmer. For instance, we learn that in 1859 not much more than two thousand cwts. were imported; whereas in 1861, when the duty had been reduced prior to its final abolition, the quantity had increased to one hundred and forty-nine thousands cwts. And it also appears, that since 1863, the year of total abolition, though the imports have of course shown an enormous advance, there have still been corresponding fluctuations, regulated chiefly by the abundance of the home supply. They range in value from less than half a million sterling in 1865 to something like,—if not over, so far as we can see a million and-a-half in 1869; the figures for that year being £1,217,938. That, roughly gives the measure of the competition which our home growers have apparently to face; and they know that prices will now be kept down to a maximum level, by what are termed the foreign reserves that are always in readiness for shipping. It is likewise shown that several continental countries,—Austria, Bavaria, Belgium, Alsace, Wurtemberg, &c., &c., even the Southern States of America and our own Australian colonies, have always, it appears, a large surplus to spare, of a quality too that quite equals the superior samples of the home or English growers. Indian speculators generally in hop cultivation, and our Punjab growers perhaps more especially, might do worse than ponder over the foregoing data.—*C. and M. Gazette.*

AFRICAN OPIUM.

We are indebted to the Portuguese Consul in Bombay for a copy of a report upon the Mozambique Opium Company's Farm, by Mr. M. Macgregor, C.E. Mr. Macgregor visited the farm on the 1st July 1880:—

I arrived here at 2-30 P.M. and have been all the afternoon going over the grounds, and I now beg to submit to you the following report:—

1. That on this date the 1st of July 1880, there are about one hundred and seventy-five acres of the finest land cleared; far superior, I am convinced, to any land at Malwa or in the vicinity of Lucknow in India.

2. About one hundred acres are now at this date sown, and about forty-five of these are under flower, and to all appearances must yield a very substantial crop about the end of September.

3. The whole of the ground taken by the Company is available for irrigation direct from the engines, and not only that, but the ground is of such a nature that a gentle incline enables the water to be led to any of the poppy-beds, even at the utmost point of the company's claims; in fact, a better place and more suitable soil could not have been chosen if the whole of the East Coast of Africa or even India, was searched for the cultivation of the poppy plant.

4. The poppies now in flower show a result that is not gained in India in even the very best of seasons. The bulbs on small and newly developed plants are large, round, and full of stable even in their undeveloped state; from this, I think, a great success will attend the future of this company. Failure will be entirely due to the mismanagement of the overlookers, for no fault can be attributed to the nature of the soil or the quantity of water required for the poppies, as there is abundance of the very best available soil as well as an unlimited supply of water.

5. The company is, I see, trying tobacco, but I am rather doubtful as to this plant, not as to the growing of it, but to the curing of the leaf, for I am certain a better soil never existed in India or America for either the cultivation of cotton, tobacco, or the poppy plant.

6. When you look at the nice little steamer, *Lady Nyassa*, of Messrs. Moir, and look at the engine on his estate, what a comparison—one rotten through neglect, the other as good as the day it left the workshop in England. Surely there must be a mistake somewhere here, when the most expensive property is going to distruction for no reason whatever.

7. The Governor of your port came here this evening from the westward, and he as well as myself, or in fact any visitor, must at a glance see that this undertaking is one that should yield a very large return, and should the company display as much experience in curing the opium as they have displayed success in growing the poppies, a very great future, indeed, is before them.

GROUND-NUTS.

IN the natural order *Leguminosæ*, which contains such a large number of species, and plants of such varied characters, two genera are remarkable, says the *Gardeners' Chronicle*, for having individuals with a peculiar habit, namely, that of ripening their seed underground.

The first of these plants, commonly known as the ground-nut (*Arachis hypogæa*) is a trailing, straggling annual, growing about two feet high, with a thick angular, pale green, hairy stem, and spreading branches. It bears yellow papilionaceous flowers, the calyx of which has a very long and slender tube, expanding at the top into two deeply cut lips. In general appearance this calyx tube has a strong resemblance to a flower-stalk, and being of a green colour it is the more easily mistaken; it was, indeed, for a long time so mistaken. The yellow petals are inserted in the throat of the calyx. The stamens are ten in number; frequently, however, one is abortive. The filaments are united into a tube for nearly their entire length, the anthers alternately rounded and oval. The ovary at first is very small, and is seated at the bottom of the calyx tube. The style is very long and slender, projecting a short distance beyond the staminal tube. After the flower has withered or fallen off, the ovary remains very small for some time, at the end of the long stalk, which, as it grows, curves downwards, pushing the ovary into the ground, and when sufficiently deep it begins to enlarge, perfecting itself in this position beneath the surface of the soil. So necessary is this burying process that if anything occurs to prevent it, neither the ovary is increased nor are the seeds formed. When fully grown, the fruits are about 1 inch or 1½ inch long, of a dusky yellowish colour, and with a netted or reticulated surface; each pod contains usually two brownish-red seeds; sometimes, however, three are found, but very rarely.

So largely is this plant cultivated at the present time in most tropical countries for the sake of the oil contained in the seeds, that it is difficult to fix upon its native country. It is, however, considered by some authors to have probably originally come from Brazil, the other species of the genus being natives of that country. Though, as we have already said the plant is largely cultivated in nearly all tropical regions, it is in western tropical Africa that it is most extensively grown.

It is described by Mr. Monteiro, in his *Angola and the River Congo*, as perhaps the most important plant in native tropical African agriculture. Many thousand tons are grown on the west coast, large quantities being sent to Europe principally to France. The author of the interesting work above referred to considers that the Arachis is destined to become one of the most important oil seeds of the future. The plant, which is known as the Mpinda or Ginguba, is cultivated in the greatest abundance a few miles inland from the coast, where the soil and climate are both better than in the arid country near the sea. Requiring as it does a rich soil for its profitable cultivation, it is consequently chiefly grown in the bottoms of the valleys, or in marshes, or in the vicinity of rivers. The cultivation is very simple. After the ground is cleared the weeds and grass are left to dry and are then burnt off, after which the ground is dug only to the depth of a few inches by women with little hoes, which, indeed, are the only agricultural implements used. The seeds are then dropped into the ground and covered up. These operations are carried on in October and November, and the first crop of seeds which are gathered for eating in a green state is ready about April. It is, however, not till July or August that they become thoroughly ripe and fit for harvesting for commercial purposes. Several thousand tons of these seeds are annually produced in this part of Africa, the bulk of which is grown in the Mbamba country lying parallel with the coast, at a distance of from 30 to 80 miles inland, The population of this comparatively small district is said to be very large, as may be gathered from the fact that the large produce of ground-nuts are shelled by hand, and brought down to the coast on the heads of the natives.

It is found by the natives to be more profitable to sell the seeds than to express the oil themselves, therefore but little oil beyond that required for their own use is prepared by them. Formerly it was obtained in a very rude manner by first pounding the seeds into a uniform mass in a wooden mortar. A lump was then taken from the mortar, hot water poured upon it, and the whole squeezed in the hands, the oil and water running from it, which was afterwards separated. The oil is very largely used in Angola for culinary purposes. The seeds, simply reduced to a paste by being ground on a stone, are used to thicken stews and similar dishes. Mr. Monteiro describes a large plantation of ground-nuts as a very beautiful sight—"a rich expanse of the most luxuriant foliage of the brightest green, every leaf studded with diamond like drops glittering in the early sun. The ground-nut is an important part of the food of the natives, and more so in the country from Ambriz to the river Congo than south at Loanda and Benguella. It is seldom eaten raw, but roasted, and when young and green, and roasted in the husks, is really delicious eating. It is excessively oily when fully ripe, and the natives then generally eat it with, bananas, and either the raw Mandiocca root or some preparation of it, experience showing them the necessity of the admixture of a farinaceous, substance with an excessively oily food."

From India also large quantities of Arachis or ground-nut oil are exported. In some of the Southern States of America the plant is now largely grown. Marseilles is the principal centre of the trade in this soil, but enormous quantities are brought to London as well as to the chief towns of Holland and Germany. So largely is the oil developed in the seeds that it is easily obtained by simple expression either with or without heat, that produced by the cold process being of course the most valuable. The oil is of a very light colour, with a bland taste, so much resembling olive-oil that it is said to be largely used for adulterating that oil. For pharmaceutical purposes ground-nut oil is now almost exclusively used in India instead of olive-oil, and in this country its chief use is in soap-making as well as in the preparation of cold cream and other toilet adjuncts. The residue of the seeds is made into cake for feeding cattle, and has been strongly recommended on account of the oil contained in it, its sweet taste, digestibility, and its richness in flesh-formers. As food for man the seeds are used in different parts of the world, either cooked or raw. In England they are frequently seen in small shops, being eaten chiefly by children, who call them "monkey nuts." In America a sweetmeat is prepared from them by parching them and treating them with sugar; simply roasted they are said to form a good substitute for coffee, and when finely beaten up into a pulp and formed into cakes, are sold in America for use as chocolate. In Loanda the traffic in ground-nuts is very extensive, and a source of great wealth to the country. In Ambacca, one of the most populous districts of the interior, thousands of tons were until recently sold annually; at the present time this trade is said to have almost entirely ceased. In consequence of the decrease in the price of ground-nuts—from £20 to £14 per ton—there has been but little inducement for the natives to cultivate the plant except for their own consumption.

The second plant, of which we spoke at the commencement as having a similar habit to that of the Arachis of ripening the seeds beneath the earth is known as the Bambarra ground-nut (*Voandzeia subterranea*). Like Arachis it belongs to the section *papilionaceæ*. It is the only species of the genus, and is described as being a native of Africa over which continent it is widely distributed by cultivation; it also occurs abundantly under the same conditions in Brazil and other parts of South America. Besides the name of Bambarra ground-nut, by which the plant is known in Africa, it is called by the natives in Natal *Igiuhlubu*, and in Brazil *Mandubi d'Angola*. The plant is annual, creeping. The leaves are borne on long stalks, and are composed of three leaflets each, the central one itself being stalked. The flowers are yellow, papilionaceous or similar in form to those of the last described plant. The calyx is bell-shaped, and the ovary, which bears two ovules, is surmounted by a short style and a hooked stigma. The flowers are both unisexual and perfect. After the period of flowering the flower-stalks bend over and push the young fruits into the ground, where like the Arachis, they ripen their seeds. The pods, when fully grown, are about ¾ inch long, somewhat oval in shape, in colour resembling the pod of Arachis, and also marked with a net-work of ribs, but coarser and not so well defined as in the ground-nut. Each pod contains but one seed, which is shining black, marked by a small white hilum. These seeds are eaten in countries where the plant grows, either in an unripe state and boiled like peas, or in their raw state when fully ripe.

NOTES ON MANURES.

AT a recent meeting of the Posen Agricultural Society, Dr. Wildt read a paper upon the results of certain comparative experiments in manuring recently carried out upon a number of contiguous estates (Sedan, Klotnik, Baranowo, Wierzonka, and Kiekrz), upon a uniform plan. The object in view was to determine what is the fittest form and most con-

venient season in and at which to employ potash as manure. The experiments afforded the interesting proof that the prejudicial effect of potash salts upon the starch contents of potatoes, which has frequently been observed in earlier researches, is diminished in intensity in proportion to the interval that elapses between the manuring and the setting of the seed potatoes. At Wierzonka, where the potash manure was applied at the time of setting, the loss of starch in the crop, as compared with the average quantity in unmanured potatoes, was 4·82 per cent. Kiekrz where there was an interval of ten days between manuring and setting, it was 4·16 per cent ; in Zlotnik, where the interval was fifteen days, the loss was 3·77 per cent. in Baranowo, with an interval of thirty days, it was 2·85 per cent. and in Sedan, with an interval of sixty-eight days, it was 0·93 per cent. only. The action of the diffetent salts of potash was also exhibited in an interesting manner. Where the potatoes were planted very soon after the ground was manured, the sulphate of potash acted most beneficially ; next to this the chlorate, and next to the chlorate, kainit. The difference in action becomes more marked as the interval between manuring and sowing is more prolonged. Thus at Sedan, where it was of 68 days' duration, the proportions were absolutely reversed. Then there was an excess in the yield of starch per morgen of the crop over that in unmanured potatoes to the extent of 99·8lbs. in the case of the sulphate of potash, 104·8lbs, in that of the chlorate, and 125·3lbs. where kainit was employed. The practical teachings of the experiments are therefore briefly to the effect that it is advisable to apply the potash salts as long as possible before setting the potatoes, and that cheap impure preparations (such as the kainit of the Stassfurt factories) are no way inferior to the more expensive pure salts in their beneficial influence.

***

One of the most important subjects discussed by the German scientists who lately met at Baden-Baden was the agricultural value of the re-absorbed phosphoric acid in phosphorites. The German phosphorites (including Brunswick coprolities) always contain, in addition to the phosphate of lime, small quantities of clay and oxide of iron. Treated with sulphuric acid, in order to render the phosphoric acid soluble in water, these phosphates, of German origin, exhibit the disagreeable property of taking up again the phosphoric acid. After being stored for a time, a portion of the free sulphuric acid recombines with the clay and oxide of iron, and is no longer soluble in water. But Professor Petermann, of Gembouz, Belgium, Professor Grandeau, of Nancy, and others have discovered that even the phosphoric acid in the soil soluble in water combines again with lime, clay, and iron, and so becomes insoluble. They also show that combined phosphoric acid is better for loose, open, sandy, or peaty soil than soluble. It appears to be the wish of the owners of coprolite deposits, &c., that the chemists should admit the recombined phosphoric acid in their valuations of the phosphorites, and the meeting was asked to support the request. After a long discussion, it was decided not to oppose the object sought, but it was not considered that the experiments hitherto conducted were sufficient to determine the relative values of recombined and precipitated phosphoric acid. It was also resolved that further experiments should be undertaken to elucidate the matter.

***

As is well known, the excrement of bats is often used as manure in certain districts of Sardinia, France, and Hungary, where it accumulates sometimes to a depth of a foot or more in the caves and grottoes frequented by countless numbers of these animals. In reference to this subject Dr. Weigelt, Director of the Agricultural Experimental Station at Rufach, states that some years ago he collected several wheelbarrowfuls of this guano from the unused upper storey of the building, and every year since has obtained from the same place a quantity varying from 30 to 40lbs. This he has used in his kitchen garden with extremely satisfactory results. Last year he made an analysis of the excrement collected at the beginning of May. It occurs as a damp brownish-black powder, in which the undigested *débris* of the shell and wing cases of different kinds of beetles are clearly recognizable, ofte. times even retaining their original characteristic colours. It smells pungently of ammonia, and is slightly suggestive of the odour of muck. The sample examined contained 16·95 per cent. of water, and the dry substances were distributed as follows:—

Phosphoric acid	3·00 per cent.
Potash	1·59 „
Other mineral matters	13·16 „
Nitrogen	10·40 „

Hence it appears that bat guano bears a close resemblance to Peruvian guano, especially if its phosphoric acid contents be increased by the addition of suitable phosphates. In the quantities ordinarily attainable bat guano would, of course, play a very insignificant part in farming proper, but it could be turned to good account by emptying it in flower or vegetable gardens of moderate size.

***

A writer in the *Revue Industrielle* points out that the lime mixed with sawdust and sulphate of iron which is employed for the purification of gas can be turned to profitable account after it has served these purposes, as a manure of considerable fertilising power. Submitted to qualitative analysis, the presence of a certain proportion of cyanides is revealed, and quantitatively its average composition is found to be as follows:—

Carbonate of lime	54·84
Caustic lime	15·00
Organic matter and carbon	17·50
Sand and clay	12·00
Undetermined matters	1·16
	100·00

An estimate of the nitrogen gives its proportion as 0·909 per cent. From the quantity of nitrogen and assimilable lime salts which it contains, the material should, therefore, form a good manure, more especially for artificial pastures. Employed in large quantities it colours the vegetation blue in consequence of the action of the iron and hydrocyanic acid it contains, and under this influence the plants die. On the other hand, its employment in moderate proportions is attended with very good results, more especially upon clayey soils.

***

The specification, says the *Planters' Gazette*, has just been published of a patent granted to Lieutenant-Colonel Francis John Bolton and Professor James Alfred Wanklyn for "improvements in the manufacture of artificial manures and ammoniacal products" In carrying out their invention, the patentees proceed as follows:—"We evaporate urine, and succeed in obtaining the solids in a fair state of dryness, and suitable for employment as rich artificial guano, or as sources of ammoniacal salts. We mix the urine as fresh as is practicable with about one-fifth of its weight of soot or of charcoal in a granular condition, and then apply heat of about 212 deg. Fahr., or a little over until the greater part of the water has evaporated off; we then add more urine to the dried mass and continue the evaporation. We repeat this process many times, and ultimately dry up and maintain a mass consisting of urine-solids mixed with more or less charcoal, and that product is the artificial manure or ammoniacal product which we propose to manufacture. The charcoal which we find that we can advantageously employ, we obtain by taking sawdust or comminuted woody or vegetable fibres, and treat them in a closed vessel with superheated steam."

MANURIAL EXPERIMENTS.

THE following on the comparative results of different manures is extracted from an article in the *Civil and Military Gazette* reviewing the operations of the Cawnpore Experimental Farm for the past year. We have ourselves treated of the subject in a former issue, but the following brief extract is full of interest; and we therefore do not hesitate to reproduce it :—

The different manures experimented upon were bone superphosphate, dissolved guano, and a green crop of indigo ploughed in ; and the following results were obtained. The outturn of wheat per acre in maunds was as follows :—

	Mds. or	Bushels.
Bone superphosphate 2 maunds	19·8	27·
Ditto 3½ ditto	23·9	31·5
Dissolved guano 1 maund 15 seers	17·3	23·7
Ditto 2 maunds	21·6	29·6
Green crop of indigo ploughed in	17·4	23·8
No manure	14·2	19·5

From this table it will be seen that bone superphosphate is by far the most valuable of the manures tried. The dissolved guano is effective, but so costly, that the increased value of the crop does not compensate for the extra expense incurred.

The bone phosphate used costs Rs. 3-7-3 per maund, and of this sum Rs. 3-4-6 goes to buy the 17¼lbs (21·3 per cent.) of sulphuric acid which gives so much of its value as manure to the bone phosphate. The bones can, of course, be purchased at an almost nominal figure, and the supply of them may be expected to be always kept up from the large number of animals that die annually. The process of manufacture was as follows. The bones were crushed in the lever mill (*dhenkli*), worked by three coolies who, in a day of 7 hours, are able to produce 180lbs. of the dust of required fineness. The crushed bones (as dust) are then thrown into a tub and moistened with hot water and sulphuric acid equal to one-third the weight of the bones added. After standing for three or four days, 15 per cent. of dry earth is mixed with it, and it is then ready for use. The high cost of the bone superphosphate will of course put it out of the reach of the ordinary Indian agriculturist, but bone dust alone, if applied in a larger quantity than the artificial manure just mentioned, is equally good in its results, although probably its effects will not be apparent until the second crop, as it is slower in application though its effects are lasting. It is an extraordinary fact that the Indian cultivator has never realised the vast utility of the bones of his dead beasts as a manure for his land, and it is to be hoped that the experiments now being conducted with the plain bone dust may shew him its efficacy. Bones there are and always will be in abundance, as the number of horned cattle in the more densely populated districts of the N.-W. Provinces is computed to be half, that of their population, the total number cannot be less than twenty-five millions, and taking the average length of life of a beast to be ten years, this would give us two-and-a-half millions of beasts dying annually ; and as a skeleton of an ordinary bullock weighs from 40 to 50lbs., we may say that the supply of bone dust would be a million

and-a-half maunds per annum, or sufficient to manure the same number of acres once every 3 years—as often as would be required—and this at a mere nominal cost to the cultivator. The effects of dissolved guano are shortly calculated as follows, and shew that it can never be used in this country owing to its high cost :—

Difference in outturn per cent, due to guano.

	In grain.	*In straw.*	*In cash profits.*
Guano, one maund 15 seers per acre	+21	+32	−40
Guano, two maunds per acre	+37	+73	Nil.

The effects of ploughing in a crop of indigo green were found to be that the crop so treated was the tallest and, to all appearances, the heaviest on the farm, but on being cut, it was found that the indigo manure had a greater effect on the straw than on the grain. The effects as compared with a similar plot not manured, were as follows :—

Difference per cent. in grain, +22 ; in straw +80 ; in cash profits +7.

The effects of all the different manures experimented on are embodied in the following table, but only the most satisfactory results arrived at in each case have been taken :—

Manure and rate per acre.	Outturn. Per acre (in lbs.) Grain.	Outturn. Per acre (in lbs.) Straw	Outturn. Increase per cent. on unmanured produce. Grain.	Outturn. Increase per cent. on unmanured produce. Straw.	Profits. Per acre.	Profits. Increase per cent. on profits on unmanured plots.
Bone earth; 3½ mds. applied just before sowing.	1893·75	2926·78	plus. 61	plus. 76	Rs. a. p. 26 12 6	plus. 73
Guano; 2 mds. applied just before sowing.	1777·94	2880 62	51	73	15 7 1	Nil.
Green crop of indigo ploughed in three months before sowing.	1429·66	2904·82	22	80	15 8 0	plus. 7

Thin sowing, so much advocated, has been found to be not satisfactory in its results, for although the plants were incomparably finer, the crop was much lighter than that obtained by the ordinary method.

SEED-BEDS.

THE work progressing upon farms at this season of the year, naturally leads us to consider the seed-bed into which the seed is deposited and the influence which such a seed-bed is likely to exert on the coming harvest. The proper condition of the seed-bed may therefore be regarded as of the greatest importance. Although this is so self-evident that no one would think of disputing the fact, it must still be admitted that we are too much in the habit of neglecting many of the conditions which are calculated to promote the results we desire. We almost unconsciously drift into certain courses of procedure, without taking into consideration the objects in view. Custom and established usage, prescribe a certain depth as being necessary ; this quantity of earth is consequently turned over, and the natural conclusion is that we have thereby provided a satisfactory seed-bed. We forget the fact, that the roots of the plants we cultivate desire to strike more deeply into the land, and are by no means satisfied with the conventional four or five-inch seed-bed. As soon as the roots have struck well through the surface-soil, their roots endeavour to penetrate into deeper soil, but they soon find an impassable barrier, probably in the form of a plough-pan. This has been caused by the sole of the plough taking its accustomed track, and gradually pressing the soil into a hard and compact bed. These plough-pans, in course of time, become so tough, that the plough naturally glides above them, and simply renders them harder by each additional ploughing of the upper soil. In many cases, we find that from long-continued working, these plough-pans become almost as hard a rock, and constitute very formidable barriers against the progress of the roots. Thus the roots become confined within a small portion of the soil, and in their powers of searching for food are greatly limited : so also must the productive energies of the crops be limited. The cultivator consequently suffers, by reason of a decreased supply of plant-food yielding a smaller crop than he ought to have obtained.

In the preparation of the seed-beds for our crops our first consideration should be to secure for the roots as large an area of feeding-ground as possible. If, after a farmer had taken a large field, he permitted a barrier to accumulate, which prevented half of it being used common prudence would suggest the removal of the impediment. If, however, instead of doing so, the farmer, unconscious of the barrier,crowded the half of the land with the stock which would have done well upon the entire field, he would soon find that their growth and condition were unsatisfactory. To remove the barrier would be the common-sense remedy, and then he would profit by their enlarged feeding ground. The frequent existence of these plough-pans in our soils, is an equally unreasonable impediment to plant growth, and, consequently, to the more profitable cultivation of the soil. The impediment being out of sight does not lessen its power for checking the farmer's success, any more than if it were seen. Being out of sight, it is of course frequently out of the mind also, for no one would allow a similar decrease of feeding-ground above the surface. As it is, the roots of the growing crop are to a great extent kept within the four or five inches of upper soil, and they draw upon the food present so severely, that manure has to be largely supplied to enable a fair crop to be produced. To carry forward the [illegible] already used, the stock being kept within half the field, need a supply of hay to keep them making even a moderate progress. The perpetuation of this loss is only permitted because the barrier is out of sight.

This is an impediment to agricultural prosperity for which we need no legal enactments ; it is a voluntary encumbrance which will be cast aside as soon as any farmer recognises the fact that it exists. Neither will he be content to adopt the expedient of making good the damage by a supply of manure. There are many and great advantages arising from the use of manure, but when its use induces a person to neglect that thorough cultivation of the soil which is desirable, then its assistance is sadly misapplied. The important services rendered by artificial supplies of fertility, have rather induced farmers to place the mechanical condition of the soil in a secondary position. This is very undesirable, for all manures should take the position of assistants to good cultivation, and never rank as substitutes. They are both parts of a good system; each has its right and proper share of duty to perform, and it is by their combined powers the most successful results are to be secured. Tillage of the soil may for a time render the use of manure unnecessary and the employment of manure may help to cover up the necessity for perfect cultivation, but in both cases we prevent that co-operation of those agencies by which the most successful results may be obtained. Let each be well and judiciously made use of, and we shall find them valuable helpers in a good cause; but they should never stand in the position of competitors for favour.

Another and very serious disadvantage arising from the plough pans, to which reference has been made, is the interference it causes with the passage of air through the soil. We know the importance of a supply of air for the support of animal life, and although in the case of plant-life the requirement is less urgent, it is none the less necessary, for the action of the air in the soil is of the greatest importance for promoting its fertility.—*L. S. Journal.*

CARROT CULTIVATION.

AN interesting memorandum on carrot cultivation, by Mr. E. C. Buck, has appeared in the *North-Western Provinces Gazette* of the 16th instant. The subject seems to have been taken up from a famine point of view. We have always known the extreme value of carrots as diet for horses and cattle ; but Mr. Buck advocates the extensive cultivation of this excellent root as human food, especially with a view to its being used when crops fail. Mr. Buck's head Superintendent, a Bengali, has written a note on the subject, of which Mr. Buck says :—" As my head Superintendent has taken much personal interest in the inquiry, I append the greater part of his note in original." This note is carefully penned, and is highly creditable to the Baboo. It appears that the Superintendent's attention was first directed to the subject, on the occasion of a visit on duty to the Punjab frontier of the Meerut Division, where he observed large quantities of carrots being cultivated. On inquiry, he found they were intended for human food. The large extent of land under this root roused his attention, as natives of India do not, as a rule, raise a crop purely and solely for cattle food. If there be any suitable refuse when the ordinary crop is garnered, the cattle get it ; but it does not enter into a ryot's head to make the raising of cattle food a primary object. He will raise a little gram, oats, or barley, but all of these he eats himself, and such a thing as a special crop of grass, for hay or a field of roots only suitable for cattle, is unknown in India. This point seems to us to be missed by Mr. Buck -the value of this crop as cattle food. True, it is incidentally mentioned that the green tops can be available for cattle thus carrying on the old idea of only giving the cattle the incidental results of the crop. The produce per acre is set down at 200 maunds, and this, we think, might be very materially improved upon. The English outturn is given at 20 to 30 tons, or say 543 to 814 maunds per acre,—an average of 678 maunds. We do not see, therefore, why 400 maunds should not be attainable. Experiment has proved that a quarter of a seer of grain and two seers of carrots will support a man as well as three-quarters of a seer of grain, while the cost need not be over one-half of that of the grain diet. Besides the value of the root crop, an acre, which was found to yield 360 maunds of roots, gave 90 maunds of green leaves which were greedily consumed by the cattle. The cost of cultivating an acre is estimated at Rs. 21, including price of seed, and as the average selling price of carrots has been ascertained to be 8 annas per maund, the profit must be considerable.

			Rs.
360 mds. roots at 8 annas		... ...	180
Cost of cultivation	21-0-0		
Rent and taxes, say	5-0-0		
			26
Net profit	...	... ...	154

which sum does not take into account the benefit derived by the cattle from the green tops. There seem to be other uses to which this root is applied, as we are told the Mussulmans prepare sweetmeats of it, which sweetmeat the Superintendent says "is a luxury." The carrots are sown in September and October, and are ready for food in two months. This is another advantage—they do not take up much of the farmer's time.

AGRICULTURAL PROGRESS IN THE CENTRAL PROVINCES.

THE past year has happily been one of fairly suitable seasons and good harvests generally. The records of all departments testify to an improved condition of the people, and, after a period of depression caused by two years of scanty harvests, the return of better times may well have animated all classes with hope and encouragement." Such is the opening sentence of the Administration Report of the Central Provinces for 1879-80, and it is the key-note of the whole report. So true is it that India is a purely agricultural land, that nothing so powerfully affects the entire people as favorable seasons and good harvests. Notwithstanding a comparatively light rainfall, the crop was a full one. "Taking the whole acreage, there can be no doubt that in all districts the outturn was favourable ;" this is said of rice which is the principal wet-weather crop. "The spring harvest—chiefly wheat and oil seeds—was in all districts good, and in tracts excellent." The only crop which suffered seriously was cotton, and this we are told, is not largely cultivated in the Northern Division. Out of a total under crop of 15,223,066 acres, only 756,136 acres or 5 per cent. were under cotton. The entire acreage, as we have said, was 15,223,066 against 14,808,667 last year—an increase of 2·72 per cent. The total was distributed as follows :—

	Acre.	Percentage.
Rice	3,065,866 ...	26·
Wheat	2,994,321 ...	19·6
Other food-grains ...	6,022,075 ...	39·6
Oil seeds	1,228,255 ...	8 1
Cotton	756,136 ...	5·
Others	256,413 ...	1·7

The produce per acre is very light, otherwise an immense quantity of food-grains should be garnered from those 12,982,262 acres. The average production of rice is 440lbs., or say 7½ bushels of 60lbs. each, whereas the average outturn of the whole of India is 14 bushels, or just double. Cotton, again, only produces an average of 40lbs. per acre, whereas in the Punjab the average is 180lbs. Supposing an acre to be cropped twice in the year—once with rice and once with cotton—the result would be as follows, the prices being the average for the whole year :—

	Rs.	A.	P.
440lbs. rice at Rs. 3-1-2 per maund ...	16	7	10
40lbs. cotton at Rs. 16-10 per maund ...	8	1	9
Total ...	24	9	7

That is, a total gross income of Rs. 24-9-7 for the crops; surely better could be done than this. The Nagpore farm seems to have done sufficiently well to please the Chief Commissioner. We fail to see where the satisfaction finds an excuse, for we are told "no special success was obtained with any of the experimental crops." The only pleasing feature we note in the model farm report is the conclusion arrived at, that "the greater portion of the experimental farm will in future be devoted to experiments with the indigenous varieties." We have all along held that this was the legitimate work of a model farm. For experiments with exotics, a botanical garden is the place. Rent is very low, but that, while to a certain extent counter-balancing the low outturn, is no excuse for it. We can see one cause of the lower average outturn of crops in the fact that cattle are scarce in the Central Provinces ; and we consequently assume that the cultivation given to the fields is of the most superficial kind. Assuming that the half of the cattle are bullocks, we have 2,611,339 bullocks for 15,223,066 acres, or one bullock for every 5¾ acres, a number manifestly insufficient for proper cultivation. The sheep and goats only number 694,761,—a miserably small number of animals of the kinds so useful and so profitable to the farmer. It is evident from a study of the number of stock owned by the farmers that they are poor, and that, of course, precludes the possibility of any attempt at high class farming. The introduction of good communications, enabling the cultivators to convey their grain to market, or to the railway, is necessary in order to improve the material condition of these people. We observe that an effort is being made to improve the outturn of the Mohpani coal mines. During the year the out-put was 13,491 tons. The Empress Cotton Mill is getting along in a way calculated to lead to similar ventures ; the consumption of cotton was about three million pounds, and the production 1,804,513 lbs. of yarn, and 578,175lbs. of cloth, valued at Rs. 8,25,337 and Rs. 2,83,711. That there is room for an extension of the cotton manufacturing industry, is shown by the fact that there are in the Central Provinces 82,999 private looms at work, and that the value of their annual outturn is Rs. 81,21,567. The trade returns show a large falling-off, the total imports and exports having decreased from 767½ lakhs of rupees in 1878-79 to 674 lakhs in 1879-80—a decrease of 12 per cent.—*I. D. News.*

A NEW WATER LIFT.

WE hear that an invention for lifting water is being patented in India by two officers, Mr. H. W. Steel, c.s., and Major E. H. Steel, Survey of India. It is likely to prove very useful to the many Europeans who are now engaged in indigo, tea-planting, &c., in this country. The invention in question is called the Lever Drum water lift. In a recent trial, the following results were obtained. Depth of well 33ft. running down to 36ft. ; diameter of well 3ft. 6 inches ; amount of water in each lift 40 gallons ; number of lifts per hour 40 ; amount of water lifted per hour 16,000lbs. ; power employed 1 man and 1 buffalo ; duration of labour 8 hours in the 24. The cost of the first apparatus put up, and alterations made in existing plant, was Rs. 82. This cost is unnecessarily high, as the iron and wood used was found afterwards to be greatly in excess of real requirements. The cost is distributed under the following heads :—Iron 2 maunds and 6 seers, Rs 20-6 (including labour) ; wood for two uprights sheesum, Rs. 5, bamboos and oil, annas 6, wages to carpenters, Rs. 18-14, leather charsah and sewing, Rs. 9-6, ropes, Rs. 8 ; alterations to tank and conduit, Rs. 20—total Rs. 82. The inventors hope that, in time, the cultivator class will be induced to adopt the plan. It is exceedingly simple it contains no appliances with which the ordinary ryot is not well acquainted, and the ordinary village carpenter and blacksmith can make it. In thinking out the various details, the standard of intelligence which it was estimated would be required from those about to work it was put as low as possible ; in fact, the action of stooping to pick up a pice from the road was taken as the point beyond which the mind of the ordinary cultivator could not be taxed. Two wells in full working order may be seen at Ferozepore, each under the charge of an untrained villager. It is hoped that, in time, the cost of the apparatus, as detailed above, which it will be seen, includes alteration to existing plant, may be reduced to Rs. 50. We believe the royalty asked on each well will be very small. —*C. and M. Gazette.*

EUPHORBIACEÆ.

THE juice of the *Euphorbia* is said to be a protection for iron work, the following from Mr. McGibbon, Superintendent of the Cape Town Botanic Graden, has been received upon this subject :—

Since receipt of your letter of January last, I have been endeavouring to obtain more full information on the uses of *Euphorbia* juice than I possess, but I am sorry to say, without success.

Euphorbia sap is not used in any form at the Cape, nor is it an article of export. I have consulted the Customs Returns to that effect. In the neighbouring colony of Natal a patent was taken out, some years ago, for the use of *Euphorbia* sap made into a form of paint for use on ship bottoms, iron and wood, and marine structures generally. I have not learned that it is used in Natal for those purposes, nor do I find any of the sap is exported. I am told that the preparation of *Euphorbia* juice is worthless as a preventative against the attacks of *animal* life on wood or iron in water.

The species of succulent *Euphorbia* are very numerous at the Cape. The largest growing Cape sp. is *E. grandidens.* It reaches a height of 20 feet with numerous fleshy branches irregulary arranged round a straight stem. It is very abundant in the eastern districts of this colony. It bleeds freely and copiously.

Another sp. found more to the eastward and in Natal is *E. quinata* (a name of no authority I fear). This is the largest growing succulent *Euphorbia* I am acquainted with, exceeding in height *E. grandidens*, and larger in circumference than that sp. A good specimen of *E. quinata* ? is a handsome object, although of so singular aspect. The quantity of juice yielded by the tree is very plentiful. From this and the preceding sp., the sap was taken I believe for experiment. I would have much pleasure in sending you a few young plants or a lot of cuttings of both, or of other Cape species of succulent *Euphorbiaceæ*, if you desire to have them.

The *Euchlæna luxurians* succeeds fairly in certain situations, but it does not seed freely (as yet) with us. It is desirable to distribute seeds of the plant to our farmers.

FERTILIZERS.

IF we could have phosphatic fertilizers finely ground, says the *Journal of Chemistry ;* so that the product would be an impalpable dust, it would hardly be necessary to act upon burnt bones or mineral phosphates with acids. The only advantage of using acids, and changing tricalcic phosphates into bicalcic or monocalcic phosphates, is that thereby we render them more rapidly soluble, and consequently they are made ready for crops with less loss of time. The important factor in the acid treatment of bone is time ; for Nature acts slowly in fitting plant food for easy assimilation. There is, however, something more than the time gained as the chemical changes effected go beyond what naturally occurs in the soil. If we sow on our fields ground bone or mineral phosphate in their raw condition, these are acted upon by rain water which contains carbonic acid, and by this combined action we get one equivalent of lime removed, and the bicalcic phosphate is formed. This is slowly soluble in water, and is thus taken up into the circulation of plants in soluble form. Carbonic acid does not carry

the decomposition so far as the stronger acid (sulphuric) does, which changes bone powder at once over into monocalcic phosphate or superphosphate.

There is good reason to believe that monocalcic phosphate, or superphosphate, is too acid in its character to enter into the circulation of plants. If a fertilizer containing superphosphate be added to a soil containing lime, it is probable that the superphosphate, by uniting with the lime, "goes back," and becomes bicalcic phosphate, and thus it assumes the form that the bone powder does when left to spontaneous change in the soil. It will be better, then, in treating bones and mineral phophates, not to carry our work so far. By the use of one-half as much acid as is required to make superphosphate, we get as a result the bicalcic phosphate, and this we cannot doubt is the better way. In the manufacture of our home-made phosphates, we have used much less acid than is generally employed, and we like the product better. It is more lasting, it gradually nourishes crops, and is not lost by being washed out of the soil.

This whole matter of cooking plant food needs to be carefully considered, and if we are on the wrong track, let us get back into the right one as soon as possible. We can help Nature vastly, without doubt, but we must remember that Nature's laws are unerring, and whenever we do violence to her teachings or go beyond that measure of help which is permitted, we go wrong, and our interests suffer in consequence.

MINERALOGY.

LAND has a rising tendency in the Wynaad. A gentleman informed us (*Madras Mail*) to-day that he bought a piece of land in that district two years ago for eight hundred rupees, and has just accepted an offer for the same of one hundred thousand rupees, or a lakh. He will thus realise Rs. 125 for each rupee of his investment.

WE are not surprised that the gold discoveries in South India should direct attention to the same subject in Ceylon. For a long time geologists have known that there are indications in parts of the island of the presence of gold, and very recently Mr. A. C. Dixon discovered gold, in the Rambodde, Pusselawa, and Kurunegalle districts, and still more lately he found in the Matalle districts, specimens of "tellurium," which is said to be the invariable indication of the presence of gold. Still it by no means follows that the precious metal exists in paying quantities. We see it stated that sulphur has been found in the Matalle district in some quantity.

OF metals, India imported last year 386,150 cwt. of copper, worth Rs. 161,98,979. England sent us 328,956, cwt.; Hong-Kong 38,082 cwt., and Australia 14,444 cwt.

ALTHOUGH we have magnificent iron ore in various parts of the country, it has never yet been utilized to any great extent, We prefer apparently to pay foreigners Rs. 1,22,72,449 a year for the 2,099,127 cwt. of iron they send us, instead of using the ore that is to be found in millions of tons in this country. The same remark is applicable to lead, of which we imported 73,499 cwt., the cost of which was Rs. 10,62,958.

CHINA has sent us far more gold than any other country in the world during the last twenty-five years; then comes Australia, while England holds the third place. England, however, sent us the most silver, then comes China, and next the Straits Settlements. By far the larger portion of the imports were made at Bombay. The exports of gold were chiefly to England, to Ceylon, to Arabia, and Persia.

THE *China Mail* informs us that four mining engineers have arrived at Hong-Kong from England, having entered into a three years' engagement with Mr. Tong King-sing, the Director of the China Merchant S.S. Co., to proceed to Pekin to direct the working of a coal mine which is being opened within eighteen miles of the capital. Iron ore has been found in considerable quantities in the neighbourhood, and it is conjectured that the opening of the coal mine may lead to the establishment of iron works by the Government.

THE reason why large rubies are not more frequently met with than they are in the markets of Europe is, according to Mr. Streeter, owing to a law in force in Burmah which deprives the market of the most beautiful rubies. "Whoever finds a ruby of a certain weight (100 ticals) is bound under pain of death to deliver it up to the Financial Department of the Government." In order to avoid this penalty and loss of property, if a man be of a better position in society, he breaks it up into small pieces, thereby occasioning vast loss to Government.

GOLD, said Professor Egleton the other day, at the New York Academy of Science, has hitherto been considered by chemists as one of the most insoluble substances in Nature; but in reality it is quite soluble. Sonnestadt has shown that every ton of sea water contains 0·9 gramme of gold. This quantity is indeed extremely minute, but it must be remembered that Nature is able to compensate for this minuteness by continuing her operations through thousands and millions of years.

IT is surprising that the attention of capitalists in England and India has not been given to the manufacture of mineral oils in the East to a greater degree than at present. India and Burmah continue to import American oil, which, although it has to travel thousands of miles by sea, can yet, after paying freight, insurance, and packing charges, be sold at a profit considerably under the cost price of oil manufactured in Burmah. Considering that Upper Burmah has, ever since we have known it, exported the unrefined earth oil, and that recent findings in Arrakan have shewn that we have in British territory large deposits of the same useful substance, it is not creditable to either European or native capitalists that the public should still have to buy their requirements in this line from America. The petroleum of Arrakan is said to be of superior quality and practically inexhaustible in quantity, and yet it costs so much to refine it with present appliances that the American oil is still the only sort generally used in this province as well as in India. If our capitalists have not yet been able to refine it and make it equally safe for public use at a cheap rate as the American oil, surely it would pay them handsomely to import skilled Americans to show them how it is to be done. Are we, with the raw material at our very doors, to go on importing our supplies of refined oil from New York for ever? Considering the plentiful supply both from Upper Burmah, and now from Arrakan, this would imply that our capitalists did not possess the energy and resources usually developed amongst capitalists in Europe.

WHILE the gold mines of India are creating excitement at home and some attention in India, the coal mines of this country, of much more consequence, in reality, to the country than those of gold, are gradually working their way into importance. A contemporary says:—

From Mr. Danvers' last railway report, we see that two-thirds of the coal consumed on the Indian railway during the last official year came from native mines: the figures were 362,762 tons of Indian coal against 150,096 of English. The largest consumer, the East Indian, uses only Indian coal, The B. B. & C. I., the Madras, and the South Indian use only English and Australian coal. The same is true of the Oude and Rohilkhund, and with the exception of a very small quantity of the Eastern Bengal Railway. The Sind, Punjab, and Delhi consumed last year 43,000 tons Indian coal against 4,600 tons English. Of the State railways all excepting the Dhond and Munmar use native coal only. Last year the G. I. P. Railway consumed 37,556 tons of Indian coal, but a contract has now been made by this company with Government for 50,000 tons yearly. In this respect the railways of Bengal and the Central India have great advantage over the line in Western and Southern India, on account of their proximity to the coal fields. The coal on those lines costs from *7s. 4d.* on East Indian to *16s. 1d.* on the Eastern Bengal, while on the Baroda line the cost was *34s. 8d.* per ton, and on the Madras *36s 9d.* per ton. The enormous advantage of the native mines to the railways near enough to avail of them is very clear, and the importance of the question to India, with a total consumption by her railways of 513,000 tons annually, can hardly be exaggerated. The coal mines of India will repay many times over indirectly if not directly the labour and capital which are bestowed upon them, and they well deserve the fostering care of Government.

DIAMONDS IN INDIA.

THE *Overland Mail* states that in a paper in the forthcoming number of the *Journal of the Scientific Proceedings of the Royal Dublin Society*, Mr. V. Ball of the Geological Survey of India gives an account of the mode of occurrence of diamonds in India and of their distribution, and adds references to the most important authorities on the subject:—

There are in India three extensive tracts widely separated from one another in which the diamond has been sought for. The most southern of those has long borne a familiar name which is however to a certain extent a misnomer. There are no diamond mines in Golconda. This name originally applied to a capital town now represented by a deserted fort in the neighbourhood of Hyderabad, seems to have been used for a whole kingdom, but the town itself was many miles distant from the nearest of the diamond mines, and it was only the mart where the precious stones were bought and sold. The second great tract occupies an immense area between the Mahanunda and the Godavery rivers, and the third great tract is situated in Bundelcund near the capital of which Punnah, some of the principal mines are to be found. The work of the Geological Survey has demonstrated that the diamonds occur in the Vindhyan rocks of Northern India. In the upper division of this formation there is a group of clay slate (Rewah) and in the lower a group of sandstone (Semri), in both of which diamond-bearing beds are met with. It is still very doubtful, however, if a diamond has yet been found in India in its original matrix. Mr. Ball gives an account of the chief mines, describing in detail from personal observation that of Sambalpur which has now for some time ceased to be productive. The Punnah mines are still productive, yielding a mean annual produce o

between £40,000 and £60,000 a year. Europeans have attempted diamond mining in each of these three traces, but in no one instance have their operations been attended with success, and yet there does not appear to be the least ground for supposing that there has been any real exhaustion of the localities where mining is feasible. In diamond mining there must necessarily be a considerable amount of individual handwork. There are immense facilities for peculation. It would almost seem that to work it profitably, a system of slavery must be adpoted. It is therefore to be distinctly understood that, except by a mere chance diamond mining will not prove a rapid road to fortune. Still writes Mr. King "for those content with a slowly paying occupation and a hard life involving close personal supervision of the workers it would pay, provided such persons possessed capital sufficient to last them a few years."

FORESTRY.

THE Mauritius Government having lately gone to the expense of importing a forest officer from India to report on the woods and forests of the island. That gentleman has just sent in his report in which it is recommended that two or more blocks of forest, of about 10,000 acres each, be formed in the lower parts of the island, to serve as reserves for the supply of fuel and small building wood for the inhabitants of Port Louis. The creation of a Government Department is also recommended, to have special charge of the State forests. The secondary and spontaneous growth where plantations have been abandoned, if protected from injury and allowed to grow, for twenty years, would, it is believed, "reforest the island, without a cent being spent for planting." "This growth, with the existing Crown lands, mountain, and river reserves and private forests would, if saved from further destruction aggregate upwards of 100,000 acres or nearly 25 per cent. of the total area of Mauritius, of which little more than 4 per cent. is said to be under cultivation."

THE attention of the Russian authorities like that of the Bombay Government has lately been turned to the prejudicial manner in which certain districts have been affected by the wholesale destruction of trees. From the earliest ages, the vegetation in the valley of Samarcand and generally of the districts of Saraf-jansk and Sagdiana has been so luxuriant, and the climate so mild and pleasant, that it has been compared by Persian poets to paradise, and so fertile is the whole oasis, one of the largest in Central Asia, that it produces not only sufficient corn for the subsistence of its 30,000 inhabitants and of the 9,000 troops quartered in it, but is also able to export large quantities of rice and wheat every year to Bokhara. During the last ten years, however, the climate has become sensibly worse, and this deterioration is believed to be mainly attributable to the reckless way in which the forests have been cut down and extensive tracts entirely denuded of trees, partly by the native inhabitants, who burn down whole woods in order to obtain charcoal easily, and partly by the Russians to procure the building material they required when they took possession of the territory. Energetic measures are, however, a correspondent of a German paper states, now being taken to arrest this wholesale destruction. The felling of trees for conversion into charcoal, or to float down the river to Bokhara, is strictly prohibited; and a decree has also been issued that a certain number of trees are to be planted on every acre of irrigated ground as well as on the banks of the streams and canals. In pursuance with this order no fewer than 11,750,000 young trees were, it is said, planted last spring in the district of Samarcand.

IN accordance with the suggestions of the Inspector-General of Forests, Assam, an experimental bamboo plantation was started at the Kulsi with a view to accertain accurately the yield of fresh shoots, such as are fit for paper manufacture, per acre per annum; whether this yield can be increased by manuring, irrigating, and other treatment, and also if the yield of fresh shoots is diminished by cutting out all such annually. It must not, of course be supposed that our rulers are going in for paper manufacture, although they have competed with private enterprise for many years past in almost every direction. Their object in this case was, we understand, to utilize not their opportunity but the knowledge they might acquire. The spot selected for this plantation, the report tells us, was rich alluvial flat on the right bank of the Kulsi river, and at the foot of the hill on which the plantation bungalow stands. The species used were the "Jati" and "Bijuli," bamboos, of which stocks with roots were first planted in June 1879, at distances of 12 feet by 12 feet, and by the end of that month, nearly all put out new shoots; but most of them subsequently died, owing, Mr. Mein thinks, to the fact, that they had not sufficient time to establish themselves in the ground and for making new roots by the time the heavy rains set in which flooded the plantation for a short time. Information as to the best time of year for planting was obtained from the villagers, rather unsafe guides, as it now turns out upon inquiry that, they plant bamboos in a rather haphazard way, frequently losing 50 per cent. of the stocks put down.

FROM the report of Dr. Thwaites on the Peradeniya Gardens (Ceylon) we extract the following on mahogany :—

A very considerable supply of seeds of this valuable tree has been received during the year from Jamaica. These seeds arrived in excellent condition for germinating, and a large number of young plants raised from them are growing here and are ready for distribution to those applying for them. To the Government agents of those provinces suitable for the cultivation of the tree have been sent supplies of seeds with instructions as to the best mode of raising them. Some seeds have also been forwarded to the conservators of forests, and others in India and elsewhere. The few old trees which are growing in this island produce seeds very sparingly indeed, so that supplies of seed from elsewhere are very acceptable from time to time. In this garden, unfortunately, the mahogany trees are liable to the attack, periodically of a lepidopterous borer which checks the growth of the young shoots, and consequently of the tree itself, materially.

"JHUMING."

THERE is a paragragh in the Chief Commissioner's Resolution on the "Forest Report of Assam for 1880," which strikingly illustrates one of the difficulties of our rule. Dr. Hunter has truly said that the Aryan populations of India have been well studied and carefully legislated for in accordance with their racial characteristics; while non-Aryans have been almost ignored. The custom of *jhuming*—to which the paragraph objects—is probably of all others the most widespread and radical characteristic of the non-Aryan races round and beyond our borders—a very necessity of their existence as they now live. The custom, as seen among the non-Aryans, is probably as old as and co-extensive with the races practising it. It is suggestive that the implement which superseded *jhuming*, the plough—was introduced by the Aryans, who, in all probability, on arrival, found the whole of India was systematically *jhumed* where possible. The custom prevails more or less among Butias, Akas, Daflas, Abors, Miris, Mishmis, Kamtis, Singphus, Nagas, Kukis, Lushais, Sheudus, Kyens, Mrus, and doubtless many others. The Garos, Kasias, and Angami Nagas constitute a group more or less to themselves, among whom for obvious reasons, it is modified. When new forest is cleared for a *jhum* it is usually devoted, the first year, to root crops, yams, cotton, &c., and in the second year, sown with hill rice and *koni*. These being on an equal footing with jungle seeds need weeding two or three times. In the third year, jungle seeds, notably those of the larger grains borne by the wind, and scattered in millions everywhere, together with the growth of *ulu* grass, render another crop too uncertain to be worth risk, and the land is abandoned. In the plains during the rainy season the ground is cleared of weeds by ploughing in water, a hot sun assisting to convert them into manure after which the rice, already half grown, is planted out and matures ere the jungle seeds can sprout and make head. This cannot be done in the hills except with favourable situations and soil, and with great labour for terracing, which brings us to the gist of the whole subject, *i.e.*, that barring fire as in *jhuming*, of water as terracing, there is but one other alternative, *viz.*, hoeing by which land can be made and kept clean for rice. To perform the latter operation so as to eradicate *ulu* grass, requires a depth of at least a foot, but this, on a steep hill side, subject to tropical rain, would carry away both crop and vegetable soil in a few weeks. It speaks volumes as to our mismanagement of these hill races, that, though in contact with them so long, we are so ignorant of the causes of their most conspicuous and chracteristic custom that an attempt is made by one of our best Commissioners to benefit them by abolishing their only mode of cultivation.—*Englishman.*

BENGAL FOREST ADMINISTRATION.

FROM the Bengal Forest Administration Report for 1879-80, we learn that the area of reserved forest in Bengal amounts to 2,945 square miles, of which 1,581 belong to the Sunderbuns, leaving only 1,364 square miles for the rest of the three provinces. It was intended to have added 1,800 square miles to the area in 1878-79, but this addition was found impossible to complete as the necessary arrangements could not be made in time. The addition will, however, be made during the current year, and will consist of tracts in Singbheom, Chittagong, and other divisions. Mr. Gamble strongly urges on the Darjeeling tea-planters to extend the timber reserves, wherever practicable, by preparing nurseries of young plants, and by bestowing the necessary care on the seedlings to protect them until they are sufficiently grown for transplanting. He gives the names of a few suitable trees for elevations up to 7,000 feet, amongst which we remark the *toon*. This is a very hardy, fast-growing, and handsome tree.

its timber is, moreover, valuable in several ways. An area of 189 acres was added during the year to the Government plantations put out from time to time; these plantations now aggregate 958 acres. If a few hundred acres could be thus planted every where and there, over the whole country, wherever suitable localities could be found, the public would soon hear the last of famines arising from a deficient rainfall. The efforts that are now persistently made to protect forest land from fires, the result of accident, carelessness, or design have been very successful during the year. The only district where serious fires occurred, was Palamow. The firewood arrangements, in reference to the Sunderbuns, are working admirably, and the profit accruing to the department from this source is considerable. The receipts from the Sunderbuns Division for the year amounted to Rs. 1,87,324, and the expenditure to only Rs. 37,720, leaving a balance of Rs. 1,49,604.

The unreserved forests under departmental control—consist of a small tract in Julpigoree, which will eventually be brought into the reserves and of 5,100 square miles of open fo re st in Chittagong. Sir Ashley Eden regrets that the Government of India has so reduced the number of superior officers in the department in Bengal, "and the further weakening of the department by the transfer, elsewhere, of officers of local experience," that he does not see his way to give the officers so much leave as he would like. He is fully alive to the fact that, for long periods of the year, these officers are necessarily exposed "to malarious influences, which must render a fair amount of leave absolutely necessary for all." This is highly creditable to the Lieutenant-Governor, and will no doubt be appreciated by the forest officers serving in Bengal. The resolution closes with a well-merited compliment to Mr. Gamble.

THE IMPORTANCE OF FORESTS.

It is satisfactory to learn from the anniversary address of Mr. Ellery, President of the Royal Society of Victoria, Australia, that legislative measures have been taken to check the "reckless" destruction of timber in the forests of that colony, where rival owners of saw-mills chop down trees out of spite and then leave them to rot. The Department of Agriculture, supported by the new forest laws, has begun to reafforest the stripped mountain-sides with exotic as well as indigenous trees. The State nurseries at Mount Macedon are making "wonderful progress," and a valuable growth now covers a large part of the summit. From these nurseries thousands of plants are distributed to other parts of the colony; and it is remarkable that many of the European and American timber trees thrive better than the native and grow more rapidly than in their original habitation "It is intended also," says Mr. Ellery, "to sow many of our wrecked forest areas broadcast with the seeds of indigenous trees, notably the ironbark, and the same process will be tried on some of the tr eless plains to the north." With a view to proper protection of the young plantations, a beginning has been made in the establishment of a college, where young men will be trained in woodcraft and forestry, and in agricultural chemistry. By these praiseworthy means it is hoped that the climate of the colony will be ameliorated, and the ever-increasing tendency towards drought—which is the invariable accompaniment of a treeless district—arrested. The *Bombay Gazette* has for years past uniformly urged upon Government the necessity of increased attention to the very important question of forests. The area under forest must be very greatly increased, and the hills and mountains of the country unfit for cultivation must be now brought under forest protection in the general interests, especially in relation to the natural irrigation and water-supply. We give below a table showing the area under woods and forests in several European countries during the years mentioned. The areas have since been increased, generally speaking :—

Country.		Year.	Acres under woods & forests.	Percentage of total area.
Great Britain	...	1877	2,187,000	Nearly 4 per cent.
Ireland	...	1877	328,000	" 17 "
Russia	...	1872	527,426,000	" 43 "
Sweden	...	1875	40,636,000	" 41 "
Norway	...	1870	17,200,000	" 23 "
Prussia	...	1876	20,047,000	" 24 "
Baden	...	1876	1,500,000	" 36 "
Wurtemberg	...	1876	1,500,000	" 32 "
Austria Proper	...	1875	28,300,000	" 32 "
Hungary	...	1875	19,490,000	" 29 "
Switzerland	...	1877	1,900,000	" 19 "
France	...	1872	20,600,000	" 16 "

Owing to the nature of the climate of the British Islands with its abundance of atmospheric moisture and freedom from such extremes of heat and cold as are prevalent in continental Europe and tropical Asia, the forest question has received but little attention. In continental Europe the question has received and is receiving much. At the annual meeting of the Geographical Society of Vienna, it was stated by Councillor Wex that the river Volga, is decreasing in volume owing to the destruction of woods, so as to affect materially the level of the Caspian Sea and the sea of Aral. Remedial measures are being adopted. The Austrain Government are wisely desirous to conserve and utilize their now valuable forest properties, and there is a State Forest Department with a staff of 1,170 persons, 22 of whom are skilled officers of high position. The evils of denudation are however, perhaps, nowhere more signally exemplified than in Spain, and Rentzoch even goes so far as to ascribe the political decadence of Spain wholly to the destruction of the forests (March, p. 306). Although her physical conditions render a large extent of forests almost indispensable to industrial progress, Spain may be said to be the only European country, excepting Great Britain, in which there has been no legal provision for the protection of woods. It is beyond doubt that vast wooded tracts affect most powerfully the economy of the globe. Rainfall in relation to forest is not the only question; other powerful factors must be considered. Among others the following :—

1. Screening the soil from the heat of the sun's rays.
2. The immense leaf surface offered to the cooling process of radiations.
3. The copious evaporation of moisture from leaves.
4. The maintenance of equable temperature and humidity.
5. The control of the regular flow of rivers.
6. The supply of perennial streams and springs, which fertilize, benefit, and beautify a country.
7. The protection of the soil on the slopes of hills and mountains.
8. The protection from silting of wells, canals, lakes, and rivers.

The relation of woods to the natural drainage of the surface and subsoil, and especially to the permanence of the configuration of the terrestrial surface, also deserves great consideration. In a recent article we pointed out that an attempt was being made to set aside the forest policy of Sir Richard Temple, but we now learn that Sir James Fergusson—it was by his advice, when Under-Secretary of State for India, that the Forest Department was established—has entirely frustrated this attempt. And we are glad to believe this, for it is manifestly of the greatest importance that in the progressive development of this tropical country enlightened principles should influence Government in matters relating to this all-important question for the behoof of present and future generations.—*Bombay Gazette.*

GARDEN.

We learn that the proposal of a complete botanical survey of India has excited considerable interest among scientific circles at home where, we be lieve, the idea first arose. For the last dozen year the botanical survey has been the hobby of Dr. Forbes Watson and one or two other gentlemen in the India Office. The officer to whom by general consent the management of the survey was long assigned by anticipation, namely Dr. King of Calcutta, is singularly well-fitted to undertake the task. It is expected that the survey will extend over ten years; but long before the expiry of that period the surveyors would be able to supply Government with a great deal of information which would prove of the greatest practical value to the country.

No South Carolina industry has thrived more since the war than market-gardening about Charleston; and this year the shipments of strawberries have reached over 1,000,000 quarts, and those of early potatoes about 42,000 barrels.

The peach orchard of John H. Parnell in Troup country Ga. W. S. A. is the largest in the world, it covers 230 acres of land, and will probably yield $70,000 this year. Its owner is a near relative of the celebrated Charles Stewart Parnell, M.P.

The autumnal show of fruits and produce of Yezo (Japan) was held at Sappore on the 1st of October, and continued open to public inspection for six days. The *Japan Mail* says :—

The exhibits were carefully and neatly arranged in a temporary wooden building in the centre of the town. They consisted of the usual productions of the farm and garden :—potatoes of various kinds, apples, pears, plums, greengages melons, pumpkins, beetroot, grapes; the cabbages, onions, squashes, and some other vegetables exhibited being of enormous size. The rich soil of Yezo is evidently capable of producing food of the best quality and in abundance. All that appears to be wanting is a greater supply of labour and a spirit of enterprise.

Regarding the perspiration of plants, the *Gentleman's Magazine* writes :—

All who have revelled in the luxury of cultivating their own cabbages, must have noticed the big drops of water that roll about on their leaves during even the driest weather. Being most abundant in the morning, they are generally regarded as dew-drops, but this is a mistake. They are accumulations of vegetable perspiration, but nevertheless are as pure as dew-drops. Dr. J. W. Moll has investigated this subject and published in Amsterdam the result of his reseaches. In eight out of forty-two cases of different species of plants, the exudation was effected by special water-pores, in four of these by the stomata, or breathing pores; in eight other cases by stomata, and in three cases it took place at portions of the leaf containing neither stomata nor special water-pores. His general conclusion is that most plants have the power of excretion water in drops from their leaves, and that the effect of this excreting

is to relieve the plant from excessive injection by root pressure, which injection or over-supply of water would otherwise probably interfere with the respiration of the plant by choking the air passages.

THE BOTANY OF THE KURRUM VALLEY.

THE *Times* contains a brief summary of the botany of the Kurrum Valley, being an account of the work recently done there by Surgeon Major Aitchison, who, on the recommendation of Sir F. Roberts, was attached to the force as botanist in April 1879. The chief collections were made along the left back of the Kurrum river from Thull to Peiwar Kotal, and thence upon the higher plateau. The entire collection consisting of over 15,000 specimens, has been taken to Kew, and there arranged by Surgeon Major Aitchison, with the assistance of some of the staff. A botanical memoir of the Kurrum Valley, with an outline of the geography of the country traversed, has been published in the Linnæan Society's Journal. The Kurrum plains, formed of immense deposits of mountain *débris*, are in summer totally devoid of water, and in winter are covered with snow, and their aspect, therefore, is not, for a botanist, promising. But numerous extremely fertile valleys debouch upon the plain along the base of the Safed Koh. Here the botany is very interesting, and the field cultivation resembles that of the best parts of Cashmere. The limit of forest on the mountain slopes is usually reached at 11,000 feet, but occasionally extends even higher. A dense *deodar* forest occupies the ridges of the Peiwar Kotal, with *Abies smithiana* and *Pinus excelsa*. At 11,000 feet this suddenly and completely disappears, and is replaced with masses of the common juniper. This, in turn, disappears at 12,000 feet, leaving the summits of the peak perfectly bare. The forests are extensive and fine, containing splendid timber. A very handsome new *clematis*, with large flowers of a pale lemon colour, has been called after General Roberts, and a new yellow rose is among the many new specimens found and described.

INDIAN MANGOES IN JAMAICA.

SOME paper lately received from Jamaica contain a description of the first East Indian mangoes which have come to maturity in the island. So at least they are designated by the Kingston paper, which has apparently forgotten that all the Jamaica mangoes are lineal descendants of the Indian variety. In two years more a century will have elapsed since the *Mangifera Indica* was introduced into Jamaica. A French ship, bound to St. Domingo from Bourbon, or more probably, one that had called at Bourbon on its way from some Indian port, was captured by Lord Rodney, and was found to contain a collection of Indian plants, among the rest being some mangoes, which were taken to Jamaica, and grown in gardens established by the House of Assembly under Dr. Dancer. There can be no very cogent reason, therefore, why an experiment which conferred on Jamaica one of its finest and most prolific fruits should not now be repeated with equal success. The mangoes of which our contemporary speaks were originally imported from Bombay, and are doubtless specimens of the Mazagon variety, the most perfect of all the different species. It is this fact which invests the experiment just tried in Jamaica with special interest, and accounts for the difficulty which has been experienced in bringing the fruit to maturity; for it is a noted fact that the Mazagon mango, when transplanted to any other part of India, grows with difficulty and loses its distinctive flavour. The trees in question were planted in the Castleton Gardens, but would not fructify, and five years ago two plants were taken by inarching to the Hope Plantation, near Kingston, where their success is at last assured. At both places, they were under the care of the Director of Public Gardens; so it would seem that they have found in the Hope Plantation soil some of the essential qualities of their native Mazagon. The fruit is described as "in bulk and shape very similar to the yam mango, and as having a pleasant flavour of its own." The islanders, however, could not be expected to admit the superiority of the new mangoes to those which they believe to be indigenous. While admitting that they are "superior to many varieties of Jamaica mango," the writer says that "they do not in any way approach our Number Eleven, the mango *par excellence*." "They have a rosy, comely exterior, the rind is exceedingly thick, and the edible part is firm, but not stringy." The Jamaica people must be hard to please if these qualities do not represent to them a perfect mango; and we shall not be surprised if careful cultivation should prove the superiority of the Mazagon even to the incomparable "Number Eleven." Jamaica at any rate, has solved a problem which has puzzled Anglo-Indians; for we find that it is successfully exporting mangoes to various American ports, where they are already in great demand. The local paper thinks that the new variety will keep longer than others, and will easily survive the six or seven days' trip to New York; and we may soon hear of Bombay mangoes grown in Jamaica forming the *pièce de résistance* of Yankee desserts.

THE CULTURE OF THE GLADIOLUS.

DURING the summer and autumn, there are few more showy and beautiful ornaments of the flower garden than the *gladioli* or corn flags They have a stately style of growth and flowering, and their flowers embrace nearly every shade of colour in richest and most brilliant tints. When well cultivated, and when the roots are planted with some view to maintaining a succession of flower, they may be had in flower for some months, and the last spikes may be cut if not finished when frost is apprehended, and put in water, and opened in the greenhouse or in a room. They are, in fact among the most tractable of flowers.

They delight in rich liberal cultivation, indeed, they are comparatively poor without it. Deep digging or trenching is a point of the first importance in their management. The soil should, if possible, be largely composed of fresh maiden loam, but if that cannot be obtained, the best compost that can be made up for them should be made use of. Trenching should be effected as early in the winter as possible, so that the soil may be thoroughly well pulverized by frost In trenching, let the compost of manure, whichever it is determined to apply to them, be put in with the top spit so that it may be mixed with the soil about mid depth of the trench.

The best manure to use is cowdung that has been in the heap for six or nine months, during which time it should be turned frequently. If the manure or compost must of necessity be used economically, the best way to do so is to leave the application of it over till planting time, when it can be put directly about the roots. But by a little forethought, there are very few who have a garden that may not be amply supplied with compost, if not with manure, for this or any other choice flower which requires high culture.

Planting time may range from December to May in favourable districts, and where the land is light, warm, and well drained; but in less favourable conditions planting so early as December is attended with some risk to the roots, which are apt to rot when soaked with moisture during the coldest period of the winter.

Generally speaking, in Scotland it is safer to defer the first planting till the most favourable weather which can be found in February or March; that is, dry, sunny weather, when the soil may be worked without clogging the tools. When this occurs, the first plantation should be made, and successive batches may be put in at intervals of a fortnight or three weeks, according as the weather may permit, up till the second week in May, after which there is some risk that they may be too late to flower well. But much depends on the character of the season; if bright and warm, and the plants are well attended to with water, or are favoured with genial showers, they will flower freely enough even if planted in June. It is not, however, desirable to depend too much upon results that are to be brought about by an exceptionally fine season, and we would therefore advise that the last planting should be done not later than the second week in May. By planting a selection of late and early varieties at that time, a very late display of bloom may be depended upon, the early sorts will be certain to flower in any except the most adverse season, while in favourable ones the late bloomers will be sure to yield their beautiful spikes.

The roots may be planted in various ways; either in clumps or lines in the borders or beds, or they may be massed in contrast in beds edged or margined with any suitable contrasting or neutral tinted plant either in flower or in foliage. They have a beautiful effect, too, when planted in the bays of masses of dwarf shrubs, over which the taller growing varieties may rear their glowing spikes of flowers relieved and chastened by the foliage underneath and around them. Indeed, for the mere purposes of display of garden decoration, they may be grown in a great variety of ways. But when grown for the purpose of exhibition solely, they require a select position and special conditions.

The position best suited for the growth of *gladioli* for exhibition purposes, is one that is moderately sheltered, the medium of shelter being placed at some distance from the plants, so as not to shade or draw them by want of air and light. The time of planting these should be regulated by the time of the exhibition at which they are to be put in competition. If it is in July, they should be planted in February; or if that is prevented by adverse weather, let them be potted at that time, and placed in cold frames to start with the view of planting them out when the weather is sufficiently favourable. But when once they are potted, they should remain in the pots till they are well filled with roots, so that they may not be subjected to any check by having their roots disturbed, or it may be broken in the process of planting. A specially excellent compost should be made up for those which are designed for exhibition, high culture must be the rule in this case, not only that splendid spikes, but splendid flowers both as to size and substance, may be produced. For shows to be held in August or September, the planting may be done correspondingly later, but in order to have plenty of spikes for any one show, it should be kept in view that many more should be planted than will be required to make up the requisite number of spikes when the time comes to select them. Much may be done as the time approaches to regulate the condition of the spikes; shading will require to be adopted to keep the most forward back while fullest exposure to the sun in backward cases will have to be given, so as to bring as many out on the day of the show as can be managed. We have had to resort to the expedient of cutting forward spikes and putting them in a cool dark room or cellar in bottles of water, to keep them back; and also the cutting of very late spikes, and placing them also in water in the greenhouse or store, in order to bring them out in time.

The depth the roots should be planted is a matter of some importance. In exposed situations and in very light soils, we would recommend from four to five inches; and in deep heavy soils not over well drained, we should say three inches were better than any greater depth. In spring and early summer, the roots will be rendered more cool and moist by having a good mulching of manure applied to the surface of the ground before drought sets in. Staking the plants as the growth may seem to want it, is of the utmost importance, and should receive due attention.—*N. B. Agriculturist.*

TEA.

THE *Indian Tea Gazette* writes very hopefully of the attempts at tea-planting which are being tried at the Andamans.

THE total exports of tea in October 1880, were 5,842,119lbs against 4,176,789lbs. in October 1879. Total exports from commencement of season (1st May) to end of October 1880, were 26,006,897lbs; same time last year, 19,448,297lbs.

THE following have been the tea exports from 1st November to 31st October for the past four years:—

	Great Britain.	Other Ports.	Total.
	lbs	lbs	lbs
1876-77	29,105,283	266,436	29,371,719
1877-78	32,868,362	486 325	33,354,687
1878-79	34.263,252	206 092	34,469,344
1879-80	43,804,595	719,927	44,524,522

WE gladly give publicity to the following confession, which appears in a circular of a large London tea-house:—

"The increasing popularity and use of Indian teas cause us to give greater prominence to them. We are bound to admit that teas grown on the virgin soil of India do possess a fragrance and strength unattainable in any China teas."

INDIAN tea has met with a very favorable reception at Melbourne: the prices fetched were in every case above those ruling in the London market at the time of their shipment to Australia.

THE Kumaon correspondent of the *Delhi Gazette* wrote a fortnight ago:—"The tea season is all but over—unless in some exceptional cases. The crop this year, as far as I can hear, is below the average, and the yield ranges from about 4½ to under 1½ maunds per acre."

THE tea manufacturing season in the Darjeeling hills is now over and although we have no figures as to the outturn before us, we are certain that the crop will be less than was estimated at the opening of the season.

SEVERAL large grants of excellent land have been taken up in the Dumsong district (Darjeeling) for tea cultivation. Pruning has been begun within the last fortnight on a few hill gardens, and most planters have now followed suit.

EXTENSIONS in tea cultivation continue in Darjeeling and Julpigoree. In each district eight new gardens were opened during the past official year, and the total number of gardens is at present 37 in Julpigoree and 152 in Darjeeling. The area under cultivation was 11,079 acres in the former district, and 37,327 acres in the latter, and the estimated yield of the season, 411,580lbs and 5,126,460lbs respectively, or a total of 5,538,040lbs, as compared with 7,535,980lbs in 1878-79.

AT the Botanical Garden in Aichi *ken* an Indian tea-plant has been planted as an experiment. The leaves have lately been plucked and treated the same as the Uji tea, and it has been found that the product of dried tea was greater in proportion to the quantity of raw leaves used than with the Japanese plants, and that both its taste and appearance are very good. Such being the case, the outturn has been sent to the superior authorities of the *ken* for examination, with a statement that the growers are devoting their attention to the new plant.

ANENT Indian teas in Australia, a Calcutta contemporary remarks:—To those who may entertain the idea of sending their produce to the Australian market, it would be as well to point out that the colonials know nothing about the liquor of tea, and are only guided to their values by appearances. 'Small well-made Pekoes, Pekoe Souchongs, and leafy broken Pekoe Souchongs with tips, are most run after, and the smaller the boxes, the better.

IT is satisfactory to learn that the Indian contributors to the Melbourne Exhibition have been successful in attracting the attention of our colonial cousins to the products of this country, and have stimulated inquiry among the commercial classes of Australia in more than one direction. Tea, which the co-operation of the Chamber of Commerce in Calcutta with the Government of India, has, by the formation of a tea syndicate, been made prominent among the exhibits and become the subject of some excitement; and the first sales which took place just before the departure of the last mail, aroused considerable interest. The prices obtained were most satisfactory, and more than realised the expectations of the most sanguine. Considerable interest has been roused not only in Melbourne itself, but also in the inland towns, and applications have been received from all quarters for consignments of Indian teas.

A GENTLEMAN who has had great experience of tea cultivation from the time when Indian teas first became an element in the Indian export trade, writes:—

I look with great suspicion on the future of tea in India. In fact, in my opinion all tea gardens that do not produce five or six maunds an acre, must ultimately be closed—and many gardens produce under *three* maunds. When one-half the gardens in Assam and Cachar are closed, and their produce, which is now sold at a loss, ceases to be sent into the market, the price of Indian teas will rise, and the proprietors of the good gardens,—the five and six maund gardens,—will drive a good trade. It must be a case of the survival of the fittest. I have just heard of two old gardens, for one of which three proprietors have to remit £1,600 each from home to keep it barely going, for the other the single proprietor has had to send out a much larger sum. Query, would not the first loss in these cases have been the least, and will they not regret before long that they did not retire altogether? The labour difficulty has always been great, but it has got to be encountered in a far more acute form than has yet been experienced. A Government Commissioner is not an infallible means of cure, certainly, but the depression of the tea industry in this country is becoming so serious as to invite some attention on the part of the Government here and at home. The British Government now derive £1,000,000 sterling (40,000,000lbs. at 6*d.* duty) from this one item of Indian teas and yet Mr. Grant Allen asks—"Is India Worth Keeping?"

THE tea industry in Dehra Doon has increased with surprising rapidity during the last ten years. Ever since the date of our interference with Afghanistan and the occupation of Quettah, the Doon planters, as also those of Kumaon and the Kangra Valley have suffered by the closing of the Central Asian Market to their produce. Orders had previously come from Bokhara, and buyers came to the doors of the planters, gave them good prices and took the tea away in bags. Under the new *régime*, however, with Lord Ripon in India, the Central Asian tea trade has revived, which would seem to indicate a confidence in communications being kept open. A correspondent writes to the *Daily News*:—

It would be hardly fair to expect high prices all at once; but news from Umritsur raises the hopes of the planters. Indeed the Umritsur tea merchants have of late been buying liberally. The good done by tea cultivation in the Doon can scarcely be estimated. . . . . In 1848 nearly 51,000 acres of cultivable land were lying in waste. A few grants had been made ten years before to favored individuals, many of them Government officials, but failure resulted from numerous causes, such as unwieldy grants, deaths of cultivators from malaria ignorance of the grantees, and hopes of great things from Government. But subsequently Government officials were prohibited holding land by the Home Government, and there was a panic, many civilians selling their interests for almost anything offered. Immediately after that, however, the rules were relaxed, and even civilians have cultivated the Doon resources to a profit. The grants, too, under Lord Canning's rules helped European enterprise by allowing the purchase of estates in fee simple.

THE Japanese Government is acting judiciously, writes the *Japan Mail* in preventing as far as practicable any adulteration of the tea grown in the country. The attempt at sophistication reported from Kobe some time since, was, we believe, promptly suppressed and a recurrence guarded against. It is in this way that the reputation of Japan teas for purity, and the consequent demand for them, will be maintained. In China, however, notwithstanding many serious warnings, a different course is apparently adopted by the natives and a recent *Shanghai Courier* says:—"we fancy there would be fewer tea drinkers at home if people knew what some of their tea was made of. The sale and exportation of the stuff which, for the want of a better description, is called 'Maloo mixture' has been prohibited over and over again by the Mixed Court, where large quantities of it have been confiscated. Yet there seems to be still a brisk trade going on in it. The police, however, are acting with praiseworthy vigilance in the matter and are frequently making heavy seizures. Within the week, the Hongkew division, under the able direction of Mr. Stripling, have seized a couple of tons of such rubbish consisting of dried tea leaves mixed with willow leaves, and have buried it, as usual, in the waste land opposite the station. It cannot be a particularly pleasant thing for people at home to know that, before they get some of their 'tea,' Chinese coolies have stewed it down two or three times and quite finished with it themselves."

MESSRS. J. SILLAR & CO. lately called public attention at home to the fact that a large quantity of a vile mixture, fraudulently called "tea," utterly unfit for human consumption, and which had been condemned by the analyst attached to the Board of Customs, had nevertheless been allowed to be re-exported; and many writers

have been commenting on the circumstances as if it was a new thing. But, as a matter of fact, this importation of impure tea is a constant trade, and the instances of its being hindered by the authorities are sufficiently few to make the risk a comparatively small one. To all interested in the sale of Indian teas, this is a subject of peculiar moment, since the impure tea is commonly employed as a "blend." In the instance mentioned by Messrs. Sillar (which is not the latest however), the owner of this "tea" succeeded, on appeal to the Lords of the Treasury, in getting a different interpretation put upon Clause 30 of the Food and Drugs Act than that of the solicitor to the Board of Customs. A writer in the *Times* explains that "it appears that the disposal of defective or adulterated tea is vested absolutely in the Board of Customs, and they may allow it to be exported, stored, or given out for consumption, as they see fit; but if it is pronounced unfit for food by the analyst, the Act says—'the same shall be forfeited and destroyed or otherwise disposed of as the Commissioners of Customs may direct.' The Customs Board read this portion of the section as placing the tea which is unfit for food out of the pale of fitness for consumption at home or abroad, and, therefore, making the forfeiture absolute, and the mode of riddance an after question. This certainly seems the common-sense view of the question; but we understand the solicitor to the Treasury thinks otherwise, and upon his opinion and reading of the Act several thousands of chests of tea which are described by epithets which cannot be repeated here have been delivered to the owner to be shipped back to China, to re-appear probably in this market."

INDIAN TEA IN AUSTRALIA.

The Melbourne *Age* of October the 6th, thus reviews the subject of Indian tea :—

Among the more important results that are likely to accrue from our International Exhibition is a better knowledge of the various products of other States, and especially of those which are suitable to our own requirements. A cursory examination only of the courts representing the British Eastern Empire unmistakably proves that there is a strong desire growing up throughout these dependencies to extend their trade relations with Australia. Already, as a whole, the consumption of this continent is beginning to assume the position of an important factor in the markets of supply; and should our progress during the next quarter of a century equal the strides we have made during the past period, the importance of being early in the field to meet these new wants cannot be gainsayed. Indeed, the exhibits we refer to as a whole indicate very clearly that our Indian neighbours fully appreciate the possibility of finding an extensive outlet for their products in Australia and thus expect to utilize the new demand so as to keep upon a more even footing the demand with the ever-increasing supply. India to a certain extent like other countries, has been suffering of late from over-production in special products—a result due to the fact that only a single market, that of Great Britain, has been looked to for their disposal. The natural result of this over-supply in one direction has been to induce both producers and merchants to look outside their old circumscribed lines of interchange for other communities to do business with; and the opportunity of an International Exhibition in Melbourne has wisely been selected to bring under the special notice of Australians the products of British India, in the hope that a large and mutually profitable trade may spring up between the two countries.

Early in the present year we directed attention to the spirited and business-like manner in which Calcutta merchants and tea-growers had taken up this subject, and of the steps the syndicate which had the matter in hand were taking to introduce Indian teas into Australia. As the matter is one of special interest to the thousands that make up the tea-drinking portion of our community, some facts regarding these teas, at present only very partially known in Australia, will hardly be out of place. Assam, in which is included the important districts of Cachar and Sylhet, is the tea-growing district of India; the climate is very moist and extremely unhealthy. The rainfall averages from 100 to 150 inches during the year, and generally commences in April lasting until October. The plantations, or gardens as they are generally termed, on which the tea plant is cultivated, yield, as a rule, from 700 to 800 lbs. per acre. The plant begins to yield when it is three years old, but is only picked lightly. At six years the plant is assumed to have matured, and will continue to yield as long as cultivation is kept up, which is done simply by hoeing round the plants. Manuring on some estates has been successfully tried of late, but the expense involved in the process prevents the plan being generally adopted. In the hill districts, which are drier and colder than the plains, the tea plant does not thrive so well, nor does it give so large a yield, the average being only 250 to 300 lbs. per acre. Indian teas are classed under two heads. In Assam, Cachar, Sylhet, Chittagong, the Dooars and the Terai, the strong pungent brisk with a rich full-flavored liquor, teas are manufactured, whilst from the indigenous plant of the hill district of Darjeeling and the Kangra Valley come the fine soft flavoury teas which command the highest prices in both the local and English markets. The estimated crop for the whole of India this year—we are informed by Mr. D. A Sibthorpe—the representative of the Calcutta Syndicate, and one of the Indian Commissioners to the Exhibition—is 40,000,000lbs, of tea against 36,000,000lbs. for 1879 and 34,000,000lbs. in 1878. The local consumption of tea in India, owing to the fact that the natives do not use it, is small, estimated at only about 2,000,000lbs., the balance of the crop is sent to the London market, where, up to the present time, it has always found a ready sale. It will be seen, however, that the continuous large increase in the production of Indian tea necessitates further outlets. Most of the Indian tea-makers confine themselves to manufacturing four or five sorts, which are known as pekoe, broken pekoe, pekoe souchong, souchongs and broken souchongs. Pekoe and broken pekoe are the finest teas in flavour and appearance, being made from the tips of the young shoots, and hence is full of life and rich with sap : the pekoe souchong is the next leaf on the shoot, the souchong and the broken souchong following in due order. Prior to the present movement to introduce Indian teas into general use in the Australian markets, the shipments made have generally consisted of high-class flavoury teas for mixing purposes, but there is really no valid reason why these colonies should not take, as Great Britain does, a fair proportion of the common sorts for ordinary consumption. Importers as well as tea-drinkers know that the China teas which have been coming of late years to the Australian markets have, as a rule, only one feature to recommend them—that of cheapness. Although the consumer doubtless fully appreciates this, there is just the suspicion now that quality has been sacrificed to a greater extent than it should be without the drinker getting the advantage. Ninepence to a shilling per pound in bond would appear—if our sale reports are correct—to be the price ordinary distributors are buying at, yet the housewife still pays her half-crown or three shillings, so that there would seem to be a screw loose somewhere. The introduction of a competing element into the market like Indian teas will, without doubt be a boon to the consumer; for with competition we are more likely to get the quality than in its absence, while the opening up of a new branch of trade with British India will furnish us with an outlet for our own products which China has never invited.

The Melbourne *Daily Telegraph* speaking of an auction held on 14th October, says :—

Considerable interest was manifested as to the result of the first auction sale of Indian teas put on the market by Messrs. James Henty & Co., the agents for the Calcutta Tea Syndicate. The catalogue comprised 783 half-chests and cases of Darjeeling, Assam, and Cachar makes, and it is extremely satisfactory to be able to state that every lot was competed for and taken up. Hitherto from 150 to 200 packages of Indian teas at one sale have exhausted the buying powers of our market, but the well organized effort now being made, and the direction of public attention to the teas through the medium of the morning journals is having the anticipated effect. The prices realized were irregular, the best proportional rates being obtained for the low and medium grades submitted, the biddings for the finer Darjeeling not coming up to expectations. In one respect, Mr. Sibthorpe, the Syndicate's representative, has cause for satisfaction, the distribution of the teas being general throughout the trade. The sales were made in bond, the prices obtained being as follow :—Darjeeling pekoes, 2*s*. 6½*d*, to 2*s*. 7½*d*.; Assam pekoes, 2*s*. 9½*d*.; pekoes, 1*s*. 1½d. to 2*s*. 0½d.; souchongs and Assam, 1*s*. 2½d., 1*s*. 3*d*., 1*s*. 4*d*., and 1*s*. 4½ d. ! pekoe souchongs, 1*s*. 5*d* to 1*s*. 7*d*. The result of the sale will warrant the continuance of the Syndicate's operations, and henceforth regular supplies will be put on the market, and an Indian trade thereby established.

COFFEE.

A COLOMBO paper states that at no period within recent years have Ceylon coffee estates been in such undoubtedly fine and healthy condition as they are at the present time.

There has been very heavy rain at the Shevaroy, and planters are looking forward with a hope that there will be very little light coffee this season.

In the Province of Isabella (Phillipines), says the *Straits Times*, the coffee and cacao trees under cultivation have been almost totally destroyed by the recent earthquakes.

The planters in Fiji are evidently determined to take all possible precaution to keep leaf disease at arms' length. In the *Fiji Times* a planter gives out in large print, that no one is to come near him or his estate, as, so far, he has successfully kept coffee leaf disease from his property !

The value of the coffee exported from India in 1854-55, was £82,804. The value of that exported last year was £1,626,746, or nearly twenty times as much as was exported just a quarter of a century ago.

There has been a considerable increase this year in the dimensions of the coffee trade of the Madras Presidency. The quantities shipped in the six months ending the 30th September, were 139,880 cwt. in 1878, 114,874 cwt. in 1879, and 203,169 cwt. in 1880, and the value rose from 60¾ lakhs in 1878 to 89 lakhs in 1880.

We (*South of India Observer*) are receiving most favourable accounts of the prospects of coffee from South-East Wynaad, more particularly the estates in the neighbourhood of the

Ouchterlony Valley; the prospects, however, are not of *immediate* bumper crops but for 1881. The yield this year, we understand, will only be a moderate one; but this is satisfactorily accounted for by the splendid crops of last season.

A CORRESPONDENT from Mercara intimates that the yield of the coffee and cardamom plantations in the Coorg country is not likely to be good, about half what it was last year. The coffee berries are unusually late in coming to maturity, while the cardamom pods are small and short of seed.

SAYS the Bangalore Examiner :—

We are sorry to learn that in Travancore, this season, the coffee crop is a small one—about 2 cwt. to the acre—which would not pay anywhere but in Travancore, where labour is cheap, and Superintendents know their work. Estates are said to be looking much better than usual for crop time. Leaf disease has gone, an unusual occurrence so early, and though "keep down expenditure" is still the local motto, the planters have reasonable hopes, from the absence of leaf disease, of a good crop next season.

THE outturn of the season's coffee crop is, writes a Ceylon paper, better than was expected, and though the effects of the leaf disease are not wholly snuffed out, with judicious and economical management, the coffee enterprize need be in no fear. The new industries in the shape of cinchona and Liberian coffee seem to have well taken root, and large plantations of the latter are being got up principally in the low-lying districts, where the soil and the damp humid climate, and the hot steaming sun, force up the growth of the plant with marvellous rapidity. In a few years hence the extent of land under cultivation and the quantity of the produce exported will, we hope, usher in a new era in the history of our island.

THE fungus which has appeared in the coffee grub in some parts of Dimbula (Ceylon) is said to be spreading much to the discomfiture of the said grub and to the delight of the planters. On Lippakelle and Henfold plantations, the grub is said to be manifestly distressed, and success has attended efforts made to propagate the fungus. We trust specimens will be sent to Dr. Trimen and Mr. Ward. The fungus and the circumstances of its appearance ought to be peculiarly interesting to scientific men as well as to practical agriculturists.

REGARDING coffee leaf disease, a medical correspondent writes to the *Ceylon Observer* :—

"Will you call the attention of the planters to kerosine oil as a cure for leaf disease. Rs. 5 of kerosine will suffice for two or three acres and perhaps more: the stems, branches, and leaves are to be painted with a brush dipped in the oil. I should like some planter to try the experiment on a very badly affected piece of coffee, say a quarter of an acre in extent, and to give me the result through your paper."

The idea is not new. Among our "Editorial Notes" will be found a short account of some experiments with kerosine conducted by a gentleman in San Francisco, though his mode of procedure was somewhat different to that suggested by the *Observer's* correspondent.

THE coffee market is again a disappointment to planters. We believe the large Brazil crop,—says a Ceylon paper—is the principal, if not the sole cause of the present fall in prices. From a Rio Commercial Report in the *British Trade Journal* the following extract is of interest:—

The coffee season upon which we have just entered, has opened with an exceptionally large crop, which is reported to be in excellent condition. The weather has been remarkably fine and free from rain thus far, and the planters have been able to secure their crops under the most favourable auspices. The market, however, has been considerably embarrassed by the mismanagement of the Dom Pedro II. railway, which has failed to transport the crop promptly, and even when arrived, has failed to deliver it as fast as required because of new weighing regulations. The stock in hand, therefore, has been poorly assorted, and insufficient to meet current demands. Owing to the general complaints aroused by this weighing regulation, steps have been taken by the Government to increase the delivering facilities of the railway and the embarrassment has in large part disappeared.

Since then arrivals at and exports from Rio have largely increased. Another possible cause of the want of firmness is the belief held in some quarters that Ceylon and Java are to give fair average crops during 1880-81! We find in a Mincing-lane Report for the above journal the statement :—

The crop in Hayti is expected to be about 15,000 tons; in Java 50,000 tons; in Ceylon, 40,000 tons.

Now Java is not likely to give more than 40,000 tons according to the latest report, and certainly Ceylon will not exceed 35,000, if it does exceed 30,000 tons which latter is the more general estimate. But these differences are after all slight compared with the effect of the big Brazil crop. We do not think political complications or the Eastern Question have much to do with the fall in coffee: coffee is largely bought for armies in the field.

THE COFFEE PRODUCTION OF INDIA.

THE VALUE OF OFFICIAL STATISTICS.

WE should have thought that the Government would not have experienced much difficulty in giving to the public exact statistics regarding coffee-cultivation, but as a matter of fact it has either met with insurmountable difficulties in its endeavours to do so, or the returns published by the Madras Government and those issued by the Government of India have been carelessly passed through the Press. We are aware that it is almost as useless to expect exactness from a Government, as it if to expect it to help to develop the resources of the country without being called upon by its subjects to do so. There are certain discrepancies observable at a glance between the figures relating to coffee cultivation issued by the Madras Government, and those issued by the Government of India. In the Madras Administration Report, we find it stated that the total area under coffee in this presidency is as follows :—Mature plants, acres 574,951; immature plants, acres 14[illegible],251; taken up for planting, but not yet planted, acres 43,821. In the returns issued by the Government of India, we have altogether a different set of figures, as regards the acreage of land planted, the number and acreage of mature and immature plants, and the approximate yield in pounds. It is certainly not a matter of vital importance, but it is just as well that statistics by the Government and bearing its imprimatur should be tolerably accurate. We are inclined to place more reliance in the statements issued by our own Government than in those issued by the Government of India. But we have thought it our duty to point out that the two do not agree, and the disagreement can only have arisen from carelessness on the part of those who had to draw up the statements.

Whether coffee cultivation will continue to increase as it has done during the past twenty years, is somewhat doubtful. A very great portion of the best land adapted for coffee growing has been already taken up, though much of it is not as yet planted. Those who are unacquainted with coffee, must not run away with the idea when they hear a planter saying he has an estate of three or four hundred acres, that the whole of his land is under coffee. As a rule, he selects only the very best portions of it on which to plant, as in nearly every case it is impossible to utilize all the land for which he pays kist. He must necessarily keep some under grass for his cattle to feed upon, while probably many acres are to be found not worth cultivating, owing to the presence of rock, or a want of a sufficient depth of soil. Be that as it may, it is very certain that, if the figures published by Government be correct, very many planters must be losing instead of making money by their industry. We are not responsible for them, but we draw attention to them as curiosities worth studying. We have given above the figures relating to the acreage, and this is what we find stated regarding the yield. "Total approximate yield is 18,606,195lbs. or about 110lbs. per acre." Now, we should like very much to know what planter would be able to carry on his estate for two or three years if he only got an average crop of 110lbs. per acre. If the gentleman who took the trouble to write the account of coffee cultivation in the Madras Administration Report had examined his figures, he would have discovered at once, had he but checked those figures, that a mistake had been made somewhere. Even supposing the 54,591 acres of mature plants bore only 100lbs. the acre, it is evident that the aggregate yield must have been more than four times as great as that set down in the report before us, viz., 12,806,195lb. On turning to page 289 of the book issued by the Board of Revenue, we see it there stated that the exports of coffee amounted to 36,165,920lbs. in 1876-77, and that during the previous year they were 42,691,712lbs., figures which are very much nearer the actuals than those paraded at page 213. On turning to the figures published by the Government of India, we find still another account of the yield of coffee estates. We are there told that the approximate yield for 1877-78, including the Cochin and Travancore States, was 29,463,718lbs. Now can any of our planter readers tell us which set of those figures is the correct one. They are all *official* —save the mark!—and are all set out in the best of leaded type. As if these discrepancies were not sufficient in number, there is still another that remains to be noticed. The Government of India, ignoring, apparently, what the Government of Madras says on the subject, puts down the average yield per acre at 243lbs, a figure very much nearer the truth than the one given above. But neither the statistics of our own Government nor those of the Government of India agree with those of the actual exports.

Now we do not see how we can place any reliance on the other figures given us, unless some satisfactory information be forthcoming as regards those we have just quoted. We are told, for instance, that the average yield is 200lbs. per acre in the Wynaad, and the cost of cultivation Rs. 250. If these figures be true, what are we to infer from them? Let us suppose, for a moment, that coffee fetches in this country Rs. 55 the hundredweight. If 200lbs. be the outturn per acre, as stated by Government, it would not be worth more than Rs. 110 at the high price we have fixed, so that, according to Government, the planters are such extremely patriotic individuals that, in order to benefit this country, they actually spend Rs. 250 to produce what will return them but Rs. 110. The figures given by the Government of India do not, except in the one single instance of Wynaad, approach Rs. 250 as the cost of cultivation per acre. It is set down at Rs. 248 for that district, so that to grow a pound of coffee which

sel's for less than two shillings, more than two shillings are expended in cultivation. But it seems strange to us that Rs. 248 should be spent per acre in Wynaad, whereas in Tinnevelly only Rs. 80 are spent, in Coimbatore Rs. 60, and on the Shevaroys Rs. 100. We have not much doubt that the gross acreage of land taken up by planters is correctly stated by the Madras Government. But, after a very careful examination of the other figures given us, we are of opinion that they are altogether incorrect and misleading. Are the Custom-house returns to be believed, or are the figures given by the Board of Revenue to be accepted? They do not correspond, neither can they be made to do so, although there ought not to be so great a difference between them as there is. Even supposing the figures given by the Madras Government are not so recent as those given by the Government of India, and making due allowance for the variations of time, it will be nevertheless evident that one set or the other are unreliable. Perhaps the members of the Planters Association may deem it worth their while to look into these figures before the next crop is ready for plucking. They can, if they wish it, exercise a very efficient check on the returns relating to their own industry, without incurring very much expense.—*Madras Times.*

POTATO (AND ? COFFEE LEAF) FUNGUS.

THE Report of the Select Committee appointed to inquire into the best means of diminishing the frequency and extent of failures in the potato crop has just been published, and affords much valuable information on a subject of widespread interest. Although in Ireland the people are less dependant now than formerly upon this precarious root, the distress of the present year was mainly due, as the famines of 1741 and 1845-46 were due to the failure of the potato crop, whilst in other parts of the world its cultivation, is steadily on the increase. The same land which, when laid down to corn, will maintain a given number of persons, will support three times that number when used for raising potatoes, and it will be long, we fear, before Irishmen cease to rely over much on this single and uncertain vegetable. The inquiries of the Committee were principally, it may be said almost entirely, confined to obtaining information upon what is known as the potato disease, and in the course of their sittings they examined the leading living authorities on the subject. The scientific witnesses were agreed on the nature of the disease, which according to them consists in the growth of a fungus on or in the plant. The disease spreads during the summer by means of spores or seeds, which first attack the leaves of the plant, the disease then descending to the tubers. A single fungus will produce "thousands of millions" of such spores, and each of them is capable in a space of time not exceeding forty-eight hours of becoming a developed fungus, and of producing fresh spores. This almost inconceivable fecundity is sufficient to account for the rapid spread of the disease during the summer. Experts, however, are at variance as to whether the spores are wafted by the wind or atmosphere to any considerable distance; but that they can be and are largely conveyed from place to place by birds, ground game, insects, and unconscious human agency is more generally admitted. Whilst again all agree that the spores, which during the summer extend the disease from plant to plant with such fearful rapidity, are incapable of living over the winter, there is difference of opinion as to how the disease hybernates. Some hold that it is mainly carried over by the filaments which constitute the body of the fungus, and which remain sometimes attached to the outside, sometimes within the skin of the potato, in which case it would be planted with the seed, although it might, to a lesser degree, remain on the old stalks and be spread with manure; while others attach great importance to resting spores. These are sexually vitalised, and possess an infinitely greater vitality than the ordinary spores, being capable of living undeveloped and exposed to the vicissitudes of climate for as long as three years. If this theory is to be accepted, the disease must be largely carried over the winter, not only in the seed potato, but in the stalks, the manure heap, and the ground itself.

The chief essential conditions for the full development and rapid spread of the disease are said to be the coincidence of moist weather with a particular stage of the growth of the plant and development of the fungus. All the witnesses strongly objected to sowing a second crop of potatoes within a certain period in the same land; yet in Ireland, among the small farmers, it is the general practice to sow every second year on the same ground. No precautions are taken against propagating the disease from year to year through the stalks; nor, although every variety of potato deteriorates as time goes on in its disease-resisting powers does the Irish cultivator think it needful to change his seed. Neither in Ireland nor in Great Britain have the most ordinary precautions been taken to produce a certain and healthy crop. Professor Baldwin is alone in his belief in the possibility of completely stamping out the disease, but other witnesses concur in thinking that we might find or develop varieties of potatoes which would be more capable of resisting it than those hitherto produced. The Committee, however, point out that although the production of new varieties or possibly the improvement of existing varieties, by a careful selection of tubers would be a work of national importance, it does not offer to the individual who devotes himself to it much hope of remuneration. They urge therefore that whether under direct Government control or through existing Agricultural Societies subsidised by Government experimental undertakings for the creation and establishment of new varieties of the potato should be encouraged in England, Scotland, and Ireland. In the latter country the farms of the Agricultural Department of the National Board might be extended and the attention of the Superintendent specifically directed to researches on the potato disease and to the creation, selection, and establishment of new varieties of the potato; whilst in England and Scotland should the Societies decline the task Superintendents with similar duties might be appointed. A further suggestion of the Committee, that in Ireland provision should be made by authority of the Government for supplying good seed potatoes to small growers for cash payments is less likely to be generally supported.—*Echo.*

WEST AFRICAN COFFEE.

THE following extract from Mr. Jamieson's last report on the Government Botanical Gardens, Ootacamund, will be read with interest by our planter friends:—

Last year I furnished a detailed report regarding the successful introduction and cultivation of West African or Liberian coffee at Barliyar. After another year's experience I can only reiterate the opinion then expressed, that I consider the progress made and the present condition of the plants eminently satisfactory, and it is now beyond doubt that this variety of coffee when grown under conditions analagous to those at Barliyar is vastly superior to the ordinary coffee *Arabica*. Another interesting fact with regard to this coffee has been determined during the past year. Having had opportunities of examining the flowers and fruit of the plants introduced and planted at Barliyar in 1877 as true "Liberian coffee," I am now quite satisfied that it is a distinct variety from the plants received in 1874-75 as "West African coffee." There is no distinguishable difference between the leaves and habit of growth of the two varieties. The flowers of the West African are not so large, and the berries are borne in larger whorls, and are more spherical in shape than that of the true Liberian variety; but the most important difference in a commercial point of view is that the West African is a much freer and more abundant cropper than the other; it is also hardier and ripens its fruit about two months earlier than the latter, and it has never produced any abortive berries, which is frequently the case with the Liberian variety. Several hundred seeds were sold and 5,925 plants raised from last year's crop of West African Coffee, and orders have been received for 500 plants. With a view to encourage plants to take up the cultivation of this valuable coffee in suitable localities, I intend advertising plants for sale at greatly reduced prices. Our trees have not been topped or pruned, but allowed to grow in their natural form, and promise to yield a good crop this year; but no doubt the yield of fruit will be greatly increased as more care and knowledge are brought to bear on their cultivation.

COFFEE IN BRAZIL.

REGARDING coffee in Brazil, a correspondent of the *Times* writes:—

The only produce which gives fair returns, on which the country depends for half its income, is coffee, the average yearly exportation of which, between 1865 and 1870, is said to have been 164,114 tons, of the value of £10,190,000. Coffee is king in Brazil, and threatens to absorb all the productive powers of the empire, to the great dismay of those prudent economists who declaim against the folly of "carrying all their eggs in one basket." There are, it is said, 530,000,000 coffee plants in the empire, covering 1,500,000 acres, to which large additions are made year by year; the annual crop is 260 000 tons, of which 50,000 are for home consumption. And yet, though "Brazilian coffee makes up about one-half of the quantity of coffee produced in the whole world," though its excellence has been recognised at the Vienna and Philadelphia exhibitions, and rewarded with gold medals and *mention honorable*, it seems to be held of so little account in the markets that, to ensure a sale, it has to be labelled as Java, Porto Rico, Ceylon, or Mocha produce. There is room for improvement in this branch of production in Brazil, and it also admits of further extension; but, although coffee can be planted almost throughout the territory of the empire, I was assured at the well-known *fazenda*, or estate, of Baron Fara, of Rio Bonito, near Barra do Piraby, a model establishment, yielding with two adjoining estates, 2,300,000lbs. of coffee, an annual income of £60,000, that the coffee crops above the latitude of Rio Janeiro are liable to be withered by droughts, while below the latitude of San Paulo they are often nipped by frost, the most favourable soil and climate being found in the northern districts of San Paulo, where the income to be made by coffee is higher by one-third than what the Baron himself can raise out of his own model farm.

THE WORLD'S COFFEE PRODUCTION.

THE four great coffee countries of the world are Brazil, Java, Sumatra, and Ceylon. The data and figures for 1879 shew that Brazil itself has produced an extraordinary quantity of beans. Hitherto, 250,000 tons have been considered as a good yearly figure for Brazil; last year, the export alone amounted to 273,000 tons. But the consumption of coffee in the country itself now amounts to 60,000 tons, raising the total yearly products of Brazil to 333,600 tons. Fortunately for the planters in other parts of the world, coffee has grown into a necessity in the United States, and, thanks to this, its price has risen. Although the soil

of Brazil especially for coffee culture, is very extensive, yet the difficulty of obtaining labor daily becomes greater, and this renders it doubtful whether the above figure can be much exceeded. The crop in Java and Sumatra was estimated at 94,000 tons for export; the consumption of the inhabitants, although the population is double that of Brazil, is not half that of the latter country. The production in Ceylon, though greater than that of 1878 shows a falling off when compared with former years; there were in all 41,200 tons exported from the island, the native consumption being very small. Coffee is, besides, grown in Central America, in several of the South American Republics, in the British and other colonies of the West Indies, in Hayti Cuba, Porto Rico, Arabia, Mauritius, Reunion, and along the North-east coast of Africa in Liberia and the African West Coast, in Manilla, Celebes and several of the islands of the Pacific and, lastly, in British India. But the total production of all these regions does not reach half of the export of the four chief countries named above.—*New York Mercantile Review.*

CINCHONA.

WE have much pleasure in recording that Mr. J. Fergusson, Deputy Conservator in charge of the Nullumboor Teak Plantations, has for the second time, been awarded the gold medal of the Scottish Arboricultural Society for the best essay of the year. In 1879 he received the gold medal for his essay on the Teak Forests of Southern India. This year his subject was Cinchona Cultivation, and his object is to show that, in the long run, it would be better to treat cinchona as a forest tree. The plantation to be thinned over by degrees, and the best trees allowed to grow to maturity, rather than on the principle of orcharding as at present pursued.

WE learn that Mr. Cross, the Central American Cinchona Explorer, is in Ootacamund, nursing the plants brought to India by him last month. The consignment consisted of three *Calisayas* of the Santa Fé variety, six plants of the hard and soft Columbian and one Cocoa plant. These came from some three hundred miles within the Central American continent, and have cost several thousands of rupees to bring to this country. Mr. Cross will see them properly established in Ootacamund before he leaves. The Santa Fé is shown by analysis to yield ten per cent. of pure sulphate of quinine. Perhaps Mr. Cross' services might be utilized to report upon the Government Cinchona Plantations. So eminent an authority might have something to say upon the subject worth knowing.

A REPORT by Mr. David Howard has recently been forwarded to the local Government by the Secretary of State for India, on the recent importations of East Indian cinchona bark to England. Mr. Howard says that "the *Officinalis* bark from the Government plantations at Dodabetta gives us some valuable information as to the effect of age on the value of the bark. The date of the plantation from which each parcel was obtained was given, and thus a series of barks have been obtained classed as natural, mossed, and renewed from trees planted in each year from 1863 to 1867." The result of the classing was highly satisfactory, showing that as yet the bark from the oldest plantations, so far from deteriorating, continues to improve. Both the genuine and the total crystallizable alkaloid steadily increased from the bark of the 1867 plantation to that of 1864, that of 1863 plantation yielding the same quinine as that of 1864 and slightly more cinchonidine and quinidine. The particulars given by Mr. Howard are considered highly satisfactory and will be freely circulated for public information.

MR. DAVID HOWARD ON INDIAN CINCHONA BARK.

MR. DAVID HOWARD, the nephew of the chief authority on the subject, reports that recent importations of East Indian cinchona bark have thrown light on several points worthy of the notice of those interested in the subject. The *officinalis* bark from the Government Plantation at Dodabetta gives us some valuable information as to the effect of age on the value of the bark. The date of the plantations from which each parcel was obtained was given, and we thus have a series of barks, classed as natural, mossed, and renewed, from trees planted each year from 1863 to 1867. As "natural" bark from the lower stems is only obtained from trees not yet treated for "renewing," it is evident that in the older plantations the natural bark will be chiefly from the upper stem or from saplings and inferior trees, and thus, as Dr. De Vrij has shown, will be of inferior quality. The result shows this to be the case, the best parcel of natural bark being from the plantation of 1867, that from the other plantations being of uneven quality, shewing no regular variation. The mossed bark, on the other hand may fairly be taken to represent the oldest bark from the main stems in each plantation, and therefore is the best guide as to the influence age on the quality of the bark. The result is highly satisfactory, showing that as yet the bark from the oldest plantations, so far from deteriorating, continues to improve. Both the quinine and the total crystallisable alkaloid steadily increase from the bark of the 18[illegible] plantation to that of 1864, that of the 1863 plantation yielding the same q[illegible] as that of 18[illegible], and slightly more cinchonidine and quinidine.

It is certainly more likely that so regular [illegible] ression is the result of greater maturity than that the difference should be caused by any variety in the *C. officinalis* cultivated. This is a most important point, for recent importations of the bark of *C. succirubra* confirm the opinion so often expressed by my uncle, J. E. Howard, F.R.S., and by Mr. Broughton, the late Quinologist to the Indian Government ("Quinology of the East Indian Plantations," p. 71) that in this species the bark deteriorates beyond a certain age. It is difficult to say exactly what that age may be, and it probable varies according to the growth of the tree, but some of the very finest of the red bark now coming from India, as far as appearance goes, certainly seems to have passed its maximum of richness in quinine. As to the "renewed" *officinalis* bark, the time during which the different parcels have been forming is not given, nor is it stated whether it is from the first, second, or later crops, and therefore the comparison may not be accurate; but it is interesting to see that here also the older plantations show no deterioration, the best being from the 1863 plantation.

From a private plantation I have received a sample of root bark of *C. officinalis* from trees which were coppiced three years ago. It gives quinine 2·2 per cent., cinchonidine 2 per cent., quinidine 1·5 per cent., and cinchonine 3·3 per cent. The stem bark from this plantation, at the time when the trees were cut down, gave quinine 2·6 per cent., cinchonidine 1·6 per cent., cinchonine 1 per cent., and but a trace of quinidine. We find, therefore, that in this sample the ordinary tendency of root bark to produce the dextrogyrate alkaloids is developed to a most unusual degree, the percentage of quinidine is a most extraordinary one for bark from *C. officinalis*. I have also received from Darjeeling a very interesting sample of the bark of *C. succirubra* accidentally renewed. It is entirely the produce of accidental injuries to the trees (not deep enough to injure the cambium and prevent the bark forming over the whole surface), no protection whatever having been given where the bark was removed. The result is as successful as could have been expected from renewing under the most favourable conditions, the contained alkaloids being quinine 2·8 per cent., cinchonidine 1·5 per cent., cinchonine 1·2 per cent., quinidine ·1 per cent., Two parcels of the stem bark sent over at the same time from this plantation gave, first, quinine ·8 per cent., cinchonidine 1·2 per cent., cinchonine 1·2 per cent., and secondly, quinine ·9 per cent., cinchonidine 1·1 per cent. cinchonine 2·0 per cent. The improvement in value in renewed bark is therefore not owing to the covering, but is found equally in this accidentally renewed bark, and it would seem that the mossing is valuable chiefly as enabling the tree to produce the renewed bark with as little injury to its health as possible. It will probably be found that a less perfect shelter than moss may, in some circumstances, be sufficient to preserve the health of the tree under this process.

It has been proposed by M. Moens to shave off the outer layers of bark without cutting quite through the bark. No doubt the cellular portion of the bark is richer in alkaloids than the inner fibrous layer (*vide* 'Quinology of the East Indian Plantations,' by J. E. Howard, F.R.S., pp 23, 24, and 38), although the corky excrescences thrown out by the variety of *C. officinalis*, the "knotty bark of Jussieu," contain but little alkaloid (*Pharmaceutical Journal*, third series, No. 454, p. 769; 'Quinology of the East Indian Plantations' p. 70). The inner and outer portions of a sample of the bark of *C. succirubra* gave the following results:—

	Quinine.	Cinchonidine.	Cinchonine.
Inner.	·6 per cent.,	1·2 per cent.	1·4 per cent.
Outer.	1·2 „	1·4 „	1·7 „

It will be noted that not only is the total alkaloid more in the outer bark, but the quinine is in greater proportion, and therefore the outer bark would be of much greater value per pound to a manufacturer than the whole bark.

The practical value of the process chiefly depends on the effect on the tree. If when thus treated, the tree throws out fresh bark of a similar quality to that produced in the old method of renewing without greater injury to its health, the process may be successful; but of course it is essential not to cut so deeply as to injure the cambium, and thus destroy the recuperative power of the bark.

SERICULTURE.

SUCCESSFUL sericulture in Dehra Doon is now under discussion, but we hear the planters do not believe in it, nor encourage it with any warmth.

A MADRAS paper says:—It is much to be regretted that the silk industry has not been placed on a really sound footing in this presidency. Bengal has managed to make it profitable. [Some years ago, the late Mr. Cammiade laid out several lakhs of rupees in gardens for the cultivation of silkworms, and in putting up expensive machinery for reeling silk. The experiment, however,

did not say; for what reason we do not know. Probably it was owing to his want of a thorough knowledge of what was required. Worms are bred in Mysore, but the production of silk is not large.

SERICULTURE IN INDIA.

We take the following on sericulture in India from a recent issue of the *North China Herald* :—

The Government of India has been making many good efforts in late years to foster old industries and to encourage the establishment of new ones; and among others they have been stimulating sericulture. This has been in rather a languid condition from the time when the factories of the East India Company passed into private hands, and since then the export of silk from India can scarcely be said to have increased. The cost of feeding the worms on mulberry leaves was too great; the worms which were reared from eggs imported from China degenerated very much; and the extension of the China Japan silk trade affected that of India unfavourably. But the attention of the Government and of private capitalists has recently been directed to the introduction of sericulture into Western India, and the reports and statements on the subject, which have been published, speak very favourably of its prospects. The cocoons of the Tusser moth are found in almost every district in Western India, and it is proposed to pay the natives a small fixed price for collecting and bringing them to agents. One pie, or less than half a farthing, for one, or as some propose for two cocoons, does not appear to be any very great encouragement to the natives, but as there will be very little trouble in collecting them from the branches of trees, it may be sufficient to procure supplies. Tusser silk has long been an article of export from India to London, but never on a very large scale. It now appears, however that experiments have proved that it can be used in the manufacture of many fabrics for which mulberry silk has hitherto solely been employed. French manufacturers of ribbon have sent out special agents to India to purchase the silks and cocoons, and are anxious that the production should be increased as much as possible. The hybridisation of the Tussar and Japanese worms has also been successful, and will no doubt improve the quality of the silk.

Grants of money to conduct further experiments in rearing the worms and treating the cocoons have been made by the Government of India, and the subject has excited considerable interest in the Bombay Presidency. If silk culture can be introduced on a large scale into Western India, it will be very advantageous to the natives and to the Government. Additional employment will be provided for the former and large tracts of land which are now covered with jungle will be cleared, so that the trees which grow on them may be made available as food for the silkworms. These trees are of several species, and are found in almost every district. It will take some years before this new trade in silk from the Bombay country can assume large proportions even if the efforts now being made to introduce it are fully successful, but it is a menace on the part of India to our most important article of export. There is no reason which we know of why silk culture should not succeed in India just as well as tea-planting. The quality of the silk may not be so fine as China's for the first few years, but with the efforts which will continually be made to improve it by the introduction of silk-worm eggs from other countries, by the application of science in crossing and rearing worms, and above all by the care which will be given to reeling the silk, all difficulties in the way of introducing it to a high position in European markets will at last be overcome. When that has been effected, the Chinese may see that it would have been better for them not to have prevented foreigners from establishing filatures in the country, as they were entitled to do under the treaty made by Lord Elgin. But by that time the world may be able to do without China silks,—at all events to a very large extent.

THE PHILADELPHIA SILK SCHOOL.

The ladies of the Silk Culture Association have reason to be encouraged in their work so far. They have opened their school with an accomplished teacher, have demonstrated that it can be supplied with fresh mulberry leaves daily from the neighbourhood of Philadelphia throughout the season, and have put themselves in correspondence with the people who want to raise silk. What is needed now is for the silk manufacturers of the country to follow the example set them by Philadelphia merchants, and contribute to the support of this school. Tall oaks from little acorns—and why not the threads of a great home industry from the cocoons of this Philadelphia School? The Women's Silk Culture Association, established during past winter, started out with the well-settled knowledge that silk could be grown in this country, as well as in any other, provided the attention of the proper growers could be called to it. Raising silkworms on a large scale in one locality may or may not be done as cheaply here as abroad, when the day's wages of the Italian or Chinese labourer is to be put against the day's wages that would have to be paid in this country. But the proper growers are the wives and daughters of the farmers throughout the country, who can give such attention as is needed, in the midst of their other occupations, precisely as they raise their chickens and eggs. But it does not pay to raise chickens and eggs at a long distance from market, while the less perishable cocoons, silkworms' eggs, or the reeled silk, can be forwarded any distance. The object of the ladies who have instituted the silk school is to teach as many learners as they can accommodate—about 125 at present—and afterwards send these out as teachers to other schools that may be established, as well as to spread the idea of cocoon culture in their own neighbourhoods at home.

The silkworm season lasts about twelve weeks for the two crops of worms; therefore the practical instruction in rearing these little workers is given from May to September. In the winter reeling is taught—that being the part of the business that demands delicate manipulation. Patterns are shown of an inexpensive reel which might be put up in any farmhouse, and where the filature can go on at odd leisure times such as women in the country have abundance of in the winter. The rearing of silkworms' eggs for exportation, and of the cocoons also, is carried on in some parts of the United States at present—in Kansas, North Carolina, and California. But the skill that accompanies silk raising in Italy, Southern France, and elsewhere, of reeling the silk, has been lost art here or rather an art that has been found wanting. The Philadelphia Silk School will teach this, as by means of the filature all the processes of silk cultivation can be carried on in this country.

The objection to raising American silk dates back to the unfortunate old multicaulis fever that ruined some speculators in trees and gave the widespread impression of a business that had been tried and found wanting. The speculation of that day, however, was confined mostly to planting tracts of mulberry trees, the prices of which ran up to fabulous sums—and all the farmers were to make their fortunes out of the sale of trees. The present experiment seems to stand on a better basis, namely, to spread the knowledge of rearing cocoons and reeling silk as an occupation for women in the country who have great difficulty in getting paying work and who are not occupied exclusively with household cares. Correspondence has brought out numerous inquiries from this class of American women, in the South as well as the North, showing that as a skilled industry there are numerous intelligent workers ready, as never before to take up such occupation. This is the right handle—if old Epictetus may be believed—of the jug, just as the inflated and unbalanced speculation in mulberry trees was decidedly the wrong one, that has lasted in prejudice to this day. Mulberry plants, however, are obtained in large numbers from Kansas, and it is said this tree will grow wherever the apple grows.

The ingenuity of our silk manufacturers has found a profitable employment for the pierced cocoons, those from which the moth has escaped, and which, pierced for rearing purposes, were supposed to be spoiled as silk. The short lengths of silk from these are now used in making up soft silk handkerchiefs, ribbons, &c., and are said to enter into the fabric of the exquisite Chuddah shawls that are such favourites at present.—*Philadelphia Ledger.*

TOBACCO.

It is said that the number of cigars smoked in Germany in 1878 was 6,504 millions. Besides these, the Germans used, during the same period, above 60,000 tons of tobacco, 8,000 tons of which had been prepared for snuff, and 700 tons for chewing.

Although American tobacco competes with the Indian product in Italy in a very vigorous way, nevertheless the trade seems, we are told, to maintain itself, nearly $1\frac{3}{4}$ million pounds having been shipped last year, valued at Rs. 98,000. This trade is capable of large increase if the good markets which exist in most of the countries of continental Europe are properly cultivated.

A correspondent at Kootiar, Trincomalie, writes to the *Ceylon Times* :—"Per this post I send you a few tobacco leaves, not a picked sample, but taken at random from a heap of about one cwt. by a coolie. I am gathering a sample prepared by Mr.——— (from Sumatra), to send home. I will send you a leaf or two of it, meanwhile you will see from this that we can grow a very fine leaf. These leaves were grown under many disadvantages and were, I think, cut rather green; (1) they were grown at the height of the drought, and were not regularly watered; (2) they received no cultivation of any kind, but were simply allowed to grow at will; and since they were cut, they were allowed to get wet, while the quantity was too small to admit of proper fermentation. But an important point is gained in the leaf being so fine."

The leaves in question, says our contemporary, are undoubtedly of the very finest variety, and have assumed all the characteristics of the Sumatra tobacco, being especially thin and silky, and of a bright golden color, well suited for the outside rolling leaf of cigars. "We look forward with interest to the more carefully prepared specimen that our correspondent is kind enough to promise to send us."

ST. PAUL'S COLLEGE is intended to supply a public School education at a moderate cost. The teaching is strictly in accordance with the principles of the Church of England.

Boys are prepared for the Universities, for Woolwich, and other competitive examinations, and, if required, for Mercantile pursuits. The inclusive charge for Board and Tuition, Washing, Medical Attendance, &c., is sixty Guineas a year.

Pupils received in January, April, and September. All applications should be made to the Warden or Sub-Warden.

A LADY and Gentleman residing nea[illegible] London, are willing to undertake the charge of two or thr[illegible] young children. Every care would be taken, a superior educatio[illegible] imparted, and the comforts of a happy Christian home provided.

The highest references will be furn[illegible]shed.

Applications for further particula[illegible] and terms should be addressed South Norwood, care of D. J. Key[illegible]er & Co., 1, Whitefriar's-street, London, E.C.

A LADY of the Church of Eng[illegible]and, who resides in a sheltered Home, receives 3 or 4 you[illegible] children from 8 to 10 years of age to be educated with her [illegible]wn little ones. They receive a Mother's care, with Educational [illegible]udiments in English, French, Latin, Music, Singing, and Drawing. Horse or Carriage exercise can be had if required for delicate childr[illegible]. Terms from 83 Guineas per annum according to requirements.

Photo of Residence and references from Clergymen and Parents of children can be had on application. Address, Mrs. John Allen Smith, Meon Hall, Chipping Campden, Gloucestershire.

TO INVESTORS.

AN excellent opportunity occurs for securing a Half Share in a well established Tea Estate, situated in a most healthy part of the Neilgherries, and only 30 hours by cart and rail from the nearest sea port. Labour and Fuel are both abundant in the neighbourhood.

The Estate which is upwards of one hundred acres in extent, comprise a large well built house with stables and offices complete, factories, &c., with machinery worked by water power. About seventy two per cent. of the acreage is under tea, more than half of which is in full bearing. There are besides about twenty thousand Gum and some Cinchona trees on the plantation. Price of Half Share, £2,750 Sterling.

N.B.—The refusal of the other half share could probably be arranged if desired.

For further particulars, apply to Nicholls & Co', 8, Old Court House-street, Calcutta, or 1 Whitefriar's-street, Fleet-street, London, E.C.

BANKS, &c.

ROYAL INSURANCE COMPANY.

The Annual Meeting of the Company was held August 1st, 1879.

LIFE DEPARTMENT.

THE total Income from Premiums in 1878 amounted to £246,514, and Interest on Investments to £90,248. The Claims by Death and Matured Policies were £153,841. After payments of all claims and expenses, £143,104 has been added to the Life Funds, which now amount to £2,389,907

The Funds of the Company now stands as follows —

Capital paid up	...	£289,545	0	0
Fire Fund	...	500,000	0	0
Reserve Fund	...	800,000	0	0
Balance, Profit and Loss	...	69,707	11	0
Life Fund	...	2,389,907	3	11
Total Funds in hand	...	**£4,049,159**	**14**	**11**

The liability of the Shareholders of the "Royal" is unlimited.

DR. JENNER'S PHOSPHOROUS.

PROVIDES the human system with thought, nerve, and brain food ; and **Charcoal** furnishes the elements of vitality, health, and strength. **Dr. Jenner's Phosphorous** and **Charcoal** are certain remedies for melancholia, nervous prostration, consumption, and impaired digestion, from whatever cause arising. Depôt, 9, Spencer-street, Park-road, Battersea, S.W., London. In bottles 2*s*. 9*d*., 4*s*. 6*d*., 11*s*., and 22*s*. From any chemist, or by post. **Dr. Jenner's Phosphorous and Charcoal** is a marvellous remedy for the **Loss of Nerve Power** and the **Arrest of Physical Decay** from whatever cause arising ; it is invaluable, and acts as a charm in **Consumption, Exhaustion,** *&c.* No Medicine known contains so much Phosphates, Soda, Magnesia, Lime, Chloride of Potassium, Iron, pure and unoxydized Phosphorous, all of which are scientifically combined in this essence, and each of which are collectively essential to the restoration of lost function.

It has received the sanction of Sir Benjamin Brodie, Sir William Lawrence, Sir Thomas Watson, Sir Charles Locock, the College of Physicians, Sir James Fergusson, Sir Philip Crampton, Sir Edward Lasketh, Sir James Clark, Dr. Miller, and Dr. Lankester. "Order **Dr. Jenner's Phosphorous** and **Charcoal**, and see that it bear the correct address of the London Depôt, 9, Spencer-street, Park-road Battersea, S.-W.; all others are a fraud. This is duly registered under the Trade Marks Act. Order Dr. Jenner's Phosphorous and Charcoal, and take no other. Order, of any Chemist in the World. London Agents: BARCLAY & SONS, Harrington-street, and all the Patent Medicine Houses.

WINES, &c.

INTRODUCED BY

W. & A. GILBEY,

SPARKLING "BRUT SAUMUR" CHAMPAGNE

FROM

FRANCE.

SECOND SHIPMENT TO THIS COUNTRY.

Just landed ex S.S. "Merkara" and in splendid condition.

Early application necessary to prevent disappointment.

"CASTLE BRUT SAUMUR"

Is the produce of selected grapes grown in the extensive wine districts of Saumur, an invaluable sparkling wine to those who require wines free from all saccharine. It is strictly what is known as a "Brut" or "Natural" wine, that is to say, no saccharine has been added since the completion of the Fermentation.

Quarts, per dozen	...	... Rs.	28 0
Pints " 2 "	...	... "	30 0

Dr. Druitt writing in the *Medical Times and Gazette* of the 29th March 1879, states as follows:—

"Added to the practical experience of the last dozen years "during which I have known these wines, I may give "the following theoretical reasons for the superiority of "*Vin Brut* as a stimulant in many cases, more par-"ticularly *dyspeptic* and others where the consumption "of sugar should be avoided.

"*First.*—The Brut wine is STOUTER and MORE GENEROUS.

"*Second.*—It is more APPETITE-COMPELLING.

"*Thirdly.*—The extra degorgement and the absence of "dosage with sugar and brandy render Brut "Saumur less liable to disagree, while it meets "for INVALIDS A WANT THAT HAS LONG BEEN FELT "by the medical profession, but which perhaps pre-"viously has not been within general grasp (*viz.*) that of "a PURE SPARKLING and MODERATELY STIMULATING "BEVERAGE at a reasonable price. The man in perfect "health may drink which he likes best, without fear of "the small quantity of sugar in the ordinary wine, but "if he prefers a dryer wine, here it is."

The following also is the report of Dr. D. Waldie, F.C.S., after analysis:—

"The results of this (analysis) indicate that the Brut Saumur is a NATURAL WINE like other NATURAL UN-"SACCHARTED OR UNFORTIFIED WINES, the nature and "properties of the constituents of which have been "ascertained, so far as I can judge, from the analysis, "it is a GOOD WHOLESOME WINE, possessing the properties "belonging to the BEST NATURAL WINES, without the "peculiarities of certain kinds, objectionable in many "cases, such as the astringency of Clarets or the "excessive amount of alcohol, or sugar in others."

With the opinions of two such well-known authorities both in England and in India, we offer the above wine to our constituents and the public.

Also to hand ex "Merkara."

A TRIAL SHIPMENT OF

W. & A. GILBEY'S OLD TOM.

It is distilled from the best UNMALTED CORN and HIGHLY RECTIFIED at Messrs. Gilbey's Own Distillery. It possesses the delicate flavour of the Juniper.

SWINBORNE'S CALVES FEET GELATINE

IS MOST NUTRITIOUS.

Invalids and Infants should take Swinborne's Isinglass in Milk, Wine, or Broth.

VEGETABLE ASH MANURE,

RECOMMENDED FOR

TEA, COFFEE, AND INDIGO,

Manufactured from the Ashes of Cow-dung, Horse-dung, &c., supplemented by Bone-dust and Potash Salt.

It is essentially a nourishing, not a forcing Manure.

The manure has been greatly improved by the successful separation of most of the useless matter and, as now manufactured, contains :—

30 per cent. of soluble Alkalies (Chloride of Potassium and Sodium, and Sulphate of Potash).
20 „ „ Lime and Magnesia.
7 „ „ Phosphoric Acid, equal to 15 per cent. of Phosphate of Lime.

The remainder being Sulphuric Acid, Iron, Carbonic Acid, organic nitrogenous matter and Silica.

The manufacturers are indebted to Messrs. Gillanders, Arbuthnot & Co. for the following Extract from the Fortnightly Report of the Manager "Burkhola Tea Estate," dated 2nd October 1878.

MANURE EXPERIMENTS.

TWO PLOTS, OF 2,793 TEA BUSHES, EACH YIELDED LEAF.

	Vegetable Ash Manure.	No Manure.
"*Up to date of last Report*	1,414lb.	1,096lb.
"*During the fortnight under Report*	260lb.	195lb.
"*Total up to date*	1,674lb.	1,291lb."

That is 30 per cent. increase in favour of the manured portion.

The manure was applied in March last, at the rate of 10 cwts. per acre, and can scarcely be said to have exerted its full influence as yet.

The Manager, "Mulla Kuttyoor Tea Concern" writes, under date September 19th, 1878, to Messrs. Begg, Dunlop & Co:—

"*The Vegetable Ash Manure I got up from you as a sample, I have tried on some sickly bushes, and its effect has certainly been beneficial.*"

Sold in strong bags, ready for shipment at Rs. 50 per ton, inclusive of bags.

A still further concentrated manure, containing 40 *per cent. of soluble Alkalies* and, additionally, 2 to 2½ per cent. of Nitrogen, specially suited for Coffee, at Rs. 65 per ton.

Delivery at the Godowns of the undersigned.

BEGG, DUNLOP & CO.,

Sole Agents.

FOR SALE.

THE Lackadie Estate, situated at the head of the Tambracherry Ghât and immediately on the Government road to Calicut, comprising by survey 598 acres of land, a considerable portion of which is virgin forest and 37 acres of Coffee.

The Estate is admirably suited for the cultivation of Coffee, Cinchona, and Tea.

There are on the Estate an excellent Bungalow and Store, both of permanent construction, timber pulping-house, and water wheel.

8 „ Sulphate of Potash.

EDE & HOBSON,

Agents for Messrs. Ohlendorff & Co.,

No. 6, New China Bazaar-street.

SEVEN PRIZE MEDALS awarded to GOODALL'S HOUSEHOLD SPECIALITIES. A single trial solicited from those who have not yet tried these preparations.

Goodall's Yorkshire Relish

THE most delicious sauce in the world; enriches hot joints, stews, chops, fish, &c.; with soup it is charming, blends admirably with all gravies; makes cold meat a luxury; makes the plainest viands palatable; the daintiest dishes more delicious; a great addition to cheese; every dish is improved by its addition; epicures pronounce it the best sauce; beware of colourable imitations.

CAUTION.—It having come to our knowledge that an imitation of our celebrated Sauce, the Yorkshire Relish, is being palmed upon purchasers, we beg that they will insist upon having the only genuine Yorkshire Relish, bearing a label with the Trade Mark, a "Willow Pattern Plate," and our name, "GOODALL, BACKHOUSE and Co., LEEDS," with a protecting label over the stopper. We are sorry that respectable tradesmen should lend themselves to such an imposture for the sake of a little extra profit. Sold by Grocers, Oilmen, Chemists, &c., in bottles, 6d., 1s., and 2s. each.

Goodall's Baking Powder

AWARDED Seven Prize Medals for superior quality. The best in the world. Defies comparison. Makes delicious puddings without eggs, pastry without butter, and beautiful light bread without yeast. One trial will convince the most sceptical of its superiority over others.

Sold by Grocers, Oilmen and Chemists, &c., in 1d. packets, 6d., 1s., 2s., and 5s. tins.

Goodall's Custard Powder

FOR making delicious custards without eggs, in less time and at half the price. Delicious to plum pudding and jam tarts; delicious to stewed rice and all kinds of fruit; delicious to everything; delicious alone.

Give it a trial.—Sold in boxes, 6d. and 1s. each, by Grocers, Chemists, Italian Warehousemen, &c.

Goodall's Egg Powder

ACKNOWLEDGED to be the only real substitute for eggs yet discovered; its action on Cakes, Puddings, &c., &c., resembles that of the egg in every particular, enriching them in colour and flavour, rendering them most wholesome and nutritious. One penny packet will go as far as four eggs! and one sixpenny tin as far as twenty-eight!

Sold everywhere, in 1d. Packets; 6d. and 1s. Tins.

Goodall's Ginger Beer Powder

MAKES three gallons of the best Ginger Beer in the world for threepence. Invaluable for producing a delicious and invigorating beverage, possessing valuable medicinal properties, thereby rendering it the most wholesome and perfect beverage ever discovered for both winter and summer use, is easily made, and acknowledged the best and cheapest.

Sold in packets, 3d. and 6d. each, by all Grocers, Chemists, and Italian Warehousemen, &c.

Goodall's Quinine Wine

IS invaluable for indigestion, nervousness, gout, rheumatics, &c. A wineglassful twice or thrice a day will be found both grateful and efficacious in all cases in which a cordial tonic is required, far superior to sherry and bitters or bitter beer.

Sold by Chemists, Grocers, &c., at 2s. per bottle.

Goodall's Mushroom Ketchup

CONFIDENTLY recommended to all true lovers of the Pure Mushroom. Prepared by a special Steam process, from the PURE JUICE, producing a FULL AND RICH FLAVOURED KETCHUP, unrivalled for its GREAT STRENGTH! PERFECT PURITY!! and UNSURPASSED FLAVOUR!!!

Sold in bottles at 6d., 1s., and 2s. each, by Grocers, Oilmen, and Italian Warehousemen, all over the kingdom.

Goodall's Brunswick Black

FOR Painting Stoves, Grates, Iron, Tin, &c. This invaluable composition is superior to any yet offered to the public, possessing great brilliancy and thoroughly protecting the articles it is applied to.

Sold in bottles at 6d. and 1s. each by Grocers, Oilmen, Chemists, Italian Warehousemen, Ship Store Dealers, &c. Shippers and the Trade supplied by the Sole Proprietors,

GOODALL, BACKHOUSE, & CO., White Horse Street, Leeds, ENGLAND.

Early application should be made to

T.,

Care of the Manager,

Bangalore.

SELLERS' QUINQUININE

Entirely supersedes Quinine, at about one-third the price.

J. SELLERS, the inventor of the process for manufacturing this article, confidently recommends it for use in India and all districts where Quinine is employed.

It is the only reliable combination of the entire alkaloids of bark, and as a tonic and antiperiodic in the treatment of Ague, Fevers, and Malarial diseases, it is superior to the Sulphate of Quinine.

It is used in several of our large Hospitals, and very extensively in private practice with the greatest satisfaction.

It resembles Quinine in appearance, and is given in the same doses as Quinine.

In an article on Cinchona and its alkaloids in the *British Medical Journal*, June 28th, 1879, the writer states:—"Sellers' Quinquinine and Howard's Quinine are equally good medicines. On this point I speak from careful observation, uninfluenced by chemical analysis, or by the statement of the vendors. Sellers' Quinquinine is similar in appearance to Howard's Quinine."

J. Sellers, the inventor and solemaker, cautions purchasers against worthless and spurious imitations which are being advertised. Every genuine package bears the label of J. Sellers, London. Sellers' Quinquinine should always be stated in orders.

Sold in 1 oz. bottles, 5s. 6d., and in 4 oz. bottles and 25 oz. tins at reduced rates.

SELLERS' MISTURA BISMUTHI COMP.,

(Registered), Stomachic and Anti-Dyspeptic, a perfect solution of Bismuth, miscible with water without precipitation, and is acknowledged to be the most useful, convenient, and efficacious preparation of Bismuth we possess; being often given with benefit when all other preparations of Bismuth have signally failed.

In cases of dyspepsia, pain after food, gastric irritation with sickness, nausea, especially due to pregnancy, and whenever there is general depression and lack of nervous energy, with loss of appetite or inability to assimilate the food, it is given with almost unfailing success. In those troublesome and difficult cases arising from sedentary habits, or excesses of any kind, so frequently met with in medical practice, it is a most reliable remedy. It is specially adapted for Indian medical practice and tropical districts.

203, Blackfriar's-road, London, S.E.
May 15th, 1879.

DEAR SIR,—I have used your Mistura Bismuthi Comp. for the last ten years, and have always found it a most reliable and useful mixture—pleasant to take, uniform in strength, and keeps for any length of time without change. I can with much confidence recommend it to my brother practitioners, for in the *many thousands* of cases in which I have prescribed it, I can safely say that I have never met with one failure. I am sure the sale would be much greater if more generally known.

Yours very truly,
T. SANDERS WORBOYS, M. R. C. S., L. S. A.

To Mr. Sellers,

It is necessary to caution the profession against spurious imitations, which do not in the smallest degree represent this preparation. All orders should specify "Sellers' Mistura Bismuthi Comp.," which is protected under the Trade Marks Act.

Each Bottle contains the exact Formula on the Label, which is Copyright.

Sold in ½lb., 1lb., 2lbs., and 6lbs. bottles at 10s. per lb.; by the Sole Maker and Originator.

THE
CALCUTTA MUSICAL ESTABLISHMENT,

No. 13/1, Government-place, East.

(LATE BURKINYOUNG & CO.)

FOUNDED, A.D. 1814.

PROPRIETOR—CHARLES GOULD.

THE SMITH AMERICAN ORGAN,

Wholly new designs and effective combinations in Reed Organs.

THE American Organ has been, and still is, the most popular and valued instrument for Churches and Chapels. Immense numbers of them are used in public worship, and it has been found that no other Reed Organs have so much sustaining power joined with such melodious quality of tone.

Style No. 10, *Seven Stops.*

This Style is furnished with two complete sets of reeds of five Octaves. Each set is divided and has a separate stop, for the upper and lower half. The upper half of the first set of reeds is named Flute, and the lower half Principal. In the second set the upper half is named Dulciana, and the lower Diapason. The first set is an Octave higher in pitch than the second, so that the instrument has practically a compass of six Octaves. By having the sets divided, it will be seen that more effect can be produced. The remaining stops are Tremolo, Diapason Forte, and Principal Forte. [*Net Cash, Rs.* 400.

Style No. 16, *Ten Stops.*

This instrument has two-and-a-half sets of reeds, and an Octave of Sub-bass. It has ten stops, *viz.*, Diapason, Dulciana, Flute, Principal Kulophon, Sub-bass, Tremolo, Principal Forte, Diapason Forte, and Octave Coupler. The last stop doubles the power of the Organ, and with the aid of the Sub-bass renders it a powerful and effective instrument for Churches and Halls; at the same time its power is not obtained at any sacrifice of delicacy, and it will be found a most desirable instrument for home use. [*Net Cash, Rs.* 650.

Style No. 20, *Nine Stops.*

This instrument has three complete sets of reeds. Two of the sets are like those in the preceding Styles, having the Principal and Forte Diapason and Dulciana stops. The third set is new and distinct in quality, the upper half is named "Aulodia" and the lower half "Fagotte." The tones of this set are unrivalled in clearness, smoothness, and tender beauty, and their effects in connection with the swell are surprising.

This Organ is one that will be approved by all persons of refined taste. [*Net Cash, Rs.* 750.

N.B.—The above prices are exclusive of packing charges.

WITH THE NUMBER OF

THE INDIAN TEA GAZETTE,

OF WEDNESDAY, MAY 19th,

WAS COMMENCED A SERIAL STORY OF MUCH INTEREST AND INSTRUCTION

TO TEA PLANTERS.

ENTITLED

JACK RAYNSFORD—Planter,

A Story (Founded on Fact)

ILLUSTRATING

The Life, Experiences, and Adventures of a Tea Planter.

The Story is being continued throughout Volume VII., and is separately paged from the rest of the *Tea Gazette*, so as to permit of its being afterwards bound up by itself.

The Work has been written by a TEA PLANTER of great experience, and will be found to afford equal instruction with recreative reading. It deals, also, with the incidents and occasion of the late Naga Raid, and other Historical Record connected with Tea in India.

The Work is copyright, and can only be obtained by present or future Subscribers to the *Tea Gazette*.

Volume VII. (No. 73 of the Series) of the *Tea Gazette* commenced with the No. of June the 2nd, but new Subscribers will receive the back issues of the Tale.

The Half-yearly advance Subscription to the Indian Tea Gazette is Rs. 9.

10, HARE-STREET, CALCUTTA.

PHŒNIX IRON WORKS,

CALCUTTA.

THE OLDEST ENGINEERING ESTABLISHMENT IN INDIA

JESSOP & CO.,

Civil and Mechanical Engineers, Contractors, Brass and Iron Founders, Metal Merchants, &c.

Forged and Cast Iron Work, Boilers, Machinery for Jute, Cotton, and Rice Mills, Collieries, Indigo Concerns, Tea Gardens, &c., Contractors and Brick-making Plant, and every class of Iron and Brass Work made to order.

SOLE AGENTS FOR

Robey & Co.'s celebrated Portable and Fixed Engines and Machinery, Gwynne & Co.'s Centrifugal Pumps, Gould's Rotary Pumps, and Robinson's Patent Steam Traps.

Importers and Manufacturers of every description of Steam Engines and Machinery.

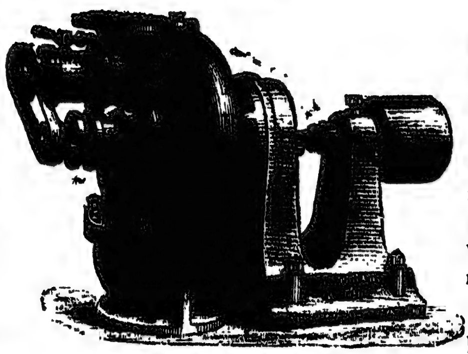
Robey & Co.'s Portable, Horizontal Fixed, and Patent "Robey" Semi-fixed Engines, Combined Vertical Engines and Boilers, Land and Marine Boilers, Gould's Rotary Power Pumps, Hand Lift and Force Pumps, Gwynne's Centrifugal Pumps, Tangye's "Special" Steam Pump, "Vauxhall" Donkey Pumps, Flour Mills, Soorkee Mills, Pug Mills, Brick-making Machines, Road Rollers, Saw Benches, Stoney's Patent Soorkee Screwing Machines and Double Acting Helical Excavators, Slide Surfacing and Screw Cutting Lathes, Drilling Machines, Punching and Shearing, Slotting and Screwing Machines, Emery Grinding Machines, Spencer's Hand Drilling Machines, Chaff Cutting Machines, Kennedy's Patent Bar Shears, Selkirk's Boiler Tube Beaders, Steam Pressure Recorders, Electric Pens, Richard's Engine Indicators, Gifford's Injectors, Cooking Stoves, Fire Proof Safes.

The following are the principal advantages of the "Invincible" Pump.

1st.—It is arranged to swivel on the bed plate, and may be placed at any angle simply by slackening a few nuts, without interfering in any way with the bed plate or the joints of either the suction or discharge pipes.

2nd.—It does not require a foot valve, being fitted with small air exhauster and clack on discharge which always keep the pump charged ready for work.

3rd.—The bearings are made on an entirely new principle, and one bearing will last out four of the old arrangements.



J. & H. GWYNNE'S
"Invincible" Centrifugal Pump.

4th.—The form of the pump casing is so arranged that one side can be taken off in a few minutes for the inspection of the whole of the disc and interior of the pump.

5th.—Hand holes are made on each side of the suction pipes to enable any foreign matter which may get into the pump or disc to be easily removed. The covers are fitted with a bayonet joint so that they can be removed and replaced in less than a minute.

6th.—The "Invincible" is 25 per cent. lighter than any other Centrifugal Pump in the market, and discharges at least 10 per cent. more water for the power applied

PRICES ON APPLICATION.

INDIGO AND TEA PLANTERS' IMPLEMENTS AND STORES.

Indigo Screws, Indigo Beaters, Indigo Pans, Indigo Pumps, Howard's Patent D and Turnwrest Ploughs, Kodallies, Pruning and Budding Knives, Grubbing Hoes, Assam Daws and Forks, Bill Hooks, American Felling Axes, Scissors, Shears, Saws, Mowing Machines, Tea Sieves, Tea Lead Solder, Galvanized Netting, Iron and Brass Wire Gauze, Leather and India-rubber Belting, Tool Chests, Grindstones, India-rubber Suction and Delivery Hose, Canvas Hose, French Wire and other Nails, Hoop Iron, Platform Weighing Machines, Spring Balances, Gram and Oat Crushing Machines, Maximum and Minimum Thermometers, Steel Band Chains for land measuring.

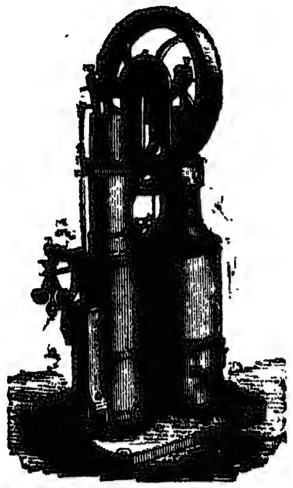
Smell.

DOES NOT REQUIRE ANY SKILLED LABOR



Specially adapted for Pumping for

EWELL, SURREY, June 13th, 1877.
MESSRS. HAYWARD, TYLER & Co.

Gentlemen,—The "Rider" Hot Air Engine you supplied some months since is working very satisfactorily. The cost of fuel is very trifling. The only attention it has had has been that of the gardener's boy, 16 years of age. I consider it the most economical pumping power I have ever seen. I should be pleased to show it to any one you may send to see it.

Yours truly, WM. KILLICK.

"DAILY TELEGRAM OFFICE," WISBEACH, May 9th, 1877.
MESSRS. HAYWARD, TYLER & Co., LONDON.

Gentlemen,—The One-Horse Hot Air Engine is now in daily work, printing off the "Daily Telegram" quite satisfactorily.

Yours truly, T. V. SUMFIELD.

WORKING PUNKAHS, HOUSEHOLD USE, OR IRRIGATION.

PATENT "UNIVERSAL" STEAM PUMPS,

FOR

IRRIGATION, MINING, OR PUMPING PURPOSES.

ECKINGTON, February 4th, 1877.
MESSRS. HAYWARD, TYLER & Co.

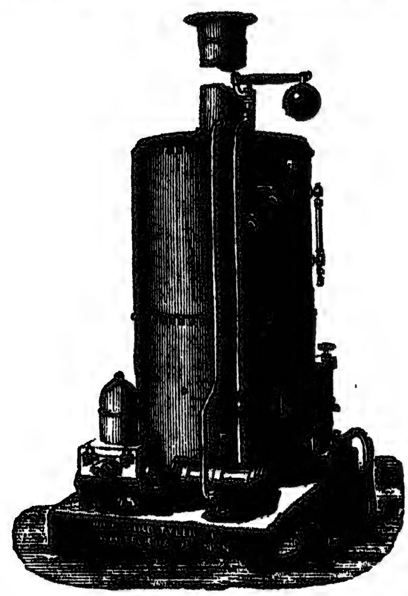
GENTLEMEN,

In reply to your inquiry, the 15 by 7 Long Stroke Pump, Messrs. Hayward, Tyler & Co. supplied us with is working remarkably well; 7 feet suction, and forcing the water 180 feet perpendicular, with 40lb. of steam.

Before putting this engine in we had one H. P. Pumping Engine, 50 inch cylinder, 9 feet stroke, and firing six boilers, 36 feet by 4 feet, to drive it; now we only require two of the above boilers to do the same work with much less annoyance and attention.

I am, Gentlemen, yours truly,

JOHN MARPLES,
Engineer of J. and G. WELLS, Eckington Collieries.



HUDDERSFIELD, January 5, 1877.
MESSRS. HAYWARD, TYLER & Co.

DEAR SIRS,

In reply to yours of 4th instant, we beg to say that the Steam Pump answers perfectly well as a Steam Fire Engine. It has now been in use over 4 years, and we find it to answer quite as well now as it did at first.

Yours truly,

Pro. B. VICKERMAN & SONS,
TOM CROWE.

BIRD & CO.,

MANUFACTURERS OF THE

PATENT IMPROVED LEATHER.—

OIL-PROOF, WATER-PROOF, IMPERISHABLE.

WORKS:—
LIME-HOUSE, LONDON, E.

THIS Leather is submitted to a patent process, rendering it stronger, more durable, and impervious to damp and heat. Being water-proof, it is particularly adapted to work in wet and exposed situations, and in the hot and moist atmosphere of the Tropics.

THE BANDS

Will stretch less than those made of ordinary leather, thus saving both the time and trouble so frequently expended in taking up belting; while for agricultural purposes, where the Bands have to remain in the open, this Leather will be found invaluable.

THE HOSE PIPING.

Besides being stronger than ordinary hose, never becomes hard, requires no oiling or dressing, and after being used, can be put away until next wanted without any further care or labour being bestowed upon it.

THE BUCKETS

Are handsomer, stronger, and lighter, and will last longer than those made of wood or iron.

THE HARNESS

Will bear exposure to the heaviest rain, only requires to be wiped with a dry cloth; neither oiling nor dressing is wanted. The leather, which is particularly recommended for Cart and Heavy Harness, though equally valuable for lighter purposes, such as Carriage Hoods, Aprons, &c.

BOOT AND SHOE PURPOSES.

The Soles and Clumps are perfectly impervious to rain and snow water, and keep the feet warm and dry in the coldest or wettest weather. Uppers can also be made waterproof.

ARMY PURPOSES.

This Patent Leather will be found most valuable and economical in the various departments of the Army, retaining its specific properties until worn out, and requiring but little care and attention; the saving in time and money, in Artillery harness alone will be great. This Leather will be found particularly adapted for use in India and all tropical climates, where the great heat and moisture prove so destructive to ordinary Leather.

GENERAL PURPOSES.

There are of course numberless other purposes to which this Leather can be applied, at, *viz*:—Pump Leathers, Portmanteaus, Bags, Gun Cases, Cartridge Boxes, Belts, Straps, &c., &c., and any information required can be obtained on application at the Works, Limehouse, London, E.

ST. PAUL'S COLLEGE is intended to supply a public School education at a moderate cost. The teaching is strictly in accordance with the principles of the Church of England.

Boys are prepared for the Universities, for Woolwich, and other competitive examinations, and, if required, for Mercantile pursuits. The inclusive charge for Board and Tuition, Washing, Medical Attendance, &c., is sixty Guineas a year.

Pupils received in January, April, and September. All applications should be made to the Warden or Sub-Warden.

A LADY and Gentleman residing near London, are willing to undertake the charge of two or three young children. Every care would be taken, a superior education imparted, and the comforts of a happy Christian home provided.

The highest references will be furnished.

Applications for further particulars and terms should be addressed South Norwood, care of D. J. Keymer & Co., 1, Whitefriar's-street, London, E.C.

A LADY of the Church of England, who resides in a sheltered Home, receives 3 or 4 young children from 3 to 10 years of age to be educated with her own little ones. They receive a Mother's care with Educational Rudiments in English, French, Latin, Music, Singing, and Drawing. Horse or Carriage exercise can be had if required for delicate children. Terms from 33 Guineas per annum according to requirements.

Photo of Residence and references from Clergymen and Parents of children can be had on application. Address, Mrs. John Allen Smith, Meon Hall, Chipping Campden, Gloucestershire.

TO INVESTORS.

AN excellent opportunity occurs for securing a Half Share in a well-established Tea Estate, situated in a most healthy part of the Neilgherries, and only 30 hours by cart and rail from the nearest sea-port. Labour and Fuel are both abundant in the neighbourhood.

The Estate which is upwards of one hundred acres in extent, comprises a large well-built house with stables and offices complete, factories, &c., with machinery worked by water power. About seventy-two per cent. of the acreage is under tea, more than half of which is in full bearing. There are besides about twenty thousand Gum and some Cinchona trees on the plantation. Price of Half Share, £2,750 Sterling.

N B.—The refusal of the other half share could probably be arranged for if desired.

For further particulars, apply to Nicholls & Co., 8, Old Court House-street, Calcutta, or 1, Whitefriar's-street, Fleet-street, London, E C.

FLAX.

A GENTLEMAN experienced in the cultivation and preparation of flax, is open to an engagement during the ensuing season.

Apply to FLAX, care of J. M. J., 10, Jackson's Ghât-street, Calcutta.

BANKS, &c.

ROYAL INSURANCE COMPANY.

The Annual Meeting of the Company was held August 1st, 1879.

SEVEN PRIZE MEDALS AWARDED.

GOODALL'S HOUSEHOLD SPECIALITIES.

A Single Trial solicited from those who have not yet tried these splendid preparations.

Goodall's Yorkshire Relish

The most delicious sauce in the world; enriches hot joints, stews, chops, fish, &c.; with soup it is charming; blends admirably with all gravies; makes cold meat a luxury; makes the plainest viands palatable; the daintiest dishes more delicious; a great addition to cheese; every dish is improved by its addition; epicures pronounce it the best sauce; beware of colourable imitations.

CAUTION.—On each label is our Trade Mark, Willow Pattern Plate, and name, GOODALL, BACKHOUSE and Co. No other is genuine.

Whatever prejudice may have existed at any time on account of its cheapness has become entirely dissipated by the daily use of this really good sauce. We merely solicit a trial from those who have not used it, after which we feel confident they will use no other sauce.

Over four million (4,000,000) bottles sold annually. Largest sale of any sauce in the world. Sold by Grocers, Oilmen, Chemists, &c., in bottles, 6d., 1s., and 2s. each.

TESTIMONIAL.—"4, Wimbourne Street, New North Road, London, N., 18th May, 1875.—Gentlemen,—I have not the pleasure of knowing you—never met you, never saw you—but still for a great length of time my sideboard has never lacked your celebrated YORKSHIRE RELISH, and it gives me very great pleasure to forward this Testimonial in its favour, provided you think it worthy of your acceptance. My sedentary habits as a writer for the magazines, &c., very often makes me exceedingly peevish with my meals, but still, no matter what I have, your YORKSHIRE RELISH always brings me to. Sometimes I have a hot joint that it enriches, sometimes cold meat that it makes exceedingly tasty and palatable—with soup it is charming. And sometimes, when the press is waiting for matter, I can make a very good make-shift for dinner with a roll steeped in it; so that in each and every sense of the word I cannot speak too highly of that which I find so good, so useful, and so cheap. If it is likely to be productive of good you are quite at liberty to publish this. —Yours truly, the Author of 'Grace Darling,' 'Harriet Stanton,' 'The Wreck of the Royal Charter,' &c.—To Goodall, Backhouse, and Co., Leeds

Goodall's Quinine Wine

The best tonic for invalids; the cheapest, because the best; invaluable for neuralgia; testimonials to its efficacy innumerable; pre-eminent for purity and strength; recommended by every one who has tried it; thousands benefited by its use; awarded seven prize medals

Highly recommended by the most eminent physicians, and acknowledged to be the best and cheapest tonic yet introduced. Strengthens the whole system, and stimulates the appetite. It is invaluable for Indigestion, Nervousness, Gout, Rheumatics, &c. Has proved an invaluable and agreeable stomachic to all suffering from general debility and loss of appetite. The best restorative for the weak, young, or aged. Is admirably adapted for delicate children and persons to whom quinine in any other form is objectionable, and is especially suited as a vehicle for the administration of Cod Liver Oil where the combined effect of Quinine and of the *Ol. Jecoris Aselli* is desirable. A wineglassful twice or thrice a day will be found both grateful and efficacious in all cases in which a cordial tonic is required—far superior to sherry and bitters or bitter beer.

[TESTIMONIAL FROM MISS EMILY FAITHFULL.]

"Victoria Press, 85, Praed Street, London, W., 20th August, 1874.

"Dear Sirs,—Having tested your excellent Quinine Wine, I am only too glad to testify to its efficacy in neuralgia, &c., as a certain cure and preventive, which is better than cure.—Yours truly, "EMILY FAITHFULL."

Sold by Grocers, Chemists, Patent Medicine Dealers and Confectioners, in Large Bottles, at 2s. each.

Goodall's Brunswick Black

For painting stoves, grates, iron, tin, &c. This invaluable composition is superior to any yet offered to the public, possessing great brilliancy, and thoroughly protecting the article it is applied to.

Sold in bottles at 6d. and 1s. each.

Goodall's Mushroom Ketchup

This splendid speciality is confidently recommended to all true lovers of the pure mushroom. It is prepared with the utmost care from the PURE JUICE, by a special steam process, secured at great cost by the proprietors, unrivalled for producing a ketchup uniform in strength, with a FULL AND RICH FLAVOR unpossessed by any other preparation of its kind in the market. One trial is sufficient to convince all of its great strength, perfect purity, and unsurpassed flavor.

Sold in bottles at 6d., 1s., and 2s. each, by Grocers, Oilmen, and Italian Warehousemen all over the kingdom.

Goodall's Baking Powder

THE BEST BAKING POWDER IN THE WORLD.

Warranted Pure, Free from Alum, and all other Injurious Ingredients.

AWARDED SEVEN PRIZE MEDALS.	MANUFACTURED FROM THE PUREST INGREDIENTS.
UNRIVALLED for EFFICIENCY and PURITY.	TESTIMONIALS INNUMERABLE.
RECOMMENDED by ALL WHO HAVE TRIED IT.	DISPENSES WITH BREWERS' YEAST.
DEFIES COMPARISON.	GIVE IT A TRIAL.

The cheapest because the best; indispensable to every household; and an inestimable boon to housewives. Makes delicious puddings without eggs, pastry without butter, and beautiful light bread without yeast. One trial will convince the most sceptical of its superiority over others.

[TESTIMONIAL.] "New North Road, London, N., May 4, 1875.

"Gentlemen,—Your Baking Powder is decidedly the best I ever used, and I shall recommend it to all my friends, being positive that it is the VERY BEST. "MARY WILSON, Matron."

Sold everywhere in 1d. Packets, 6d., 1s. 2s., and 5s. Tins, by Grocers, Oilmen, Chemists, &c.

Goodall's Custard Powder

For making delicious Custards, without eggs, in less time and at half the price. Delicious to plum pudding, delicious to jam tarts, delicious to stewed rice, delicious to all kinds of fruit, delicious to all kinds of puddings, delicious to all kinds of fruit pies, delicious to everything, delicious alone. Unequalled for the purposes intended. Will give the utmost satisfaction if the instructions given are implicitly followed. The Proprietors entertain the greatest confidence in the article, and can recommend it to housekeepers generally as a useful agent in the preparation of a good custard. GIVE IT A TRIAL.

Sold in boxes 6d. and 1s. each by Grocers, Chemists, Italian Warehousemen, &c.

[TESTIMONIAL.] "London, 5th February, 1879.

"Gentlemen,—Your Custard Powder is simply delightful, and cannot be approached by any powder I have hitherto used. "Yours respectfully, E. P.

"To Messrs. Goodall, Backhouse, & Co., White Horse Street, Leeds."

Goodall's Ginger Beer Powder

Makes three gallons of the best Ginger Beer in the world for threepence. The most valuable preparation for the production of a delicious and invigorating beverage. This Powder stands unrivalled, possessing valuable medicinal properties to a very large extent. It is not only cooling in its nature, but also an invaluable stomachic, thereby rendering it the most wholesome and perfect beverage ever discovered for both winter and summer. It is easily made, and acknowledged to be by far the cheapest and best Ginger Beer Powder ever offered to the public.

CAUTION.—To prevent disappointment be sure and ask for GOODALL'S GINGER BEER POWDER, as most of the so-called powders are made up of inferior articles, and contain little or no Ginger. Sold in Packets, 3d. and 6d. each, by all Grocers, Chemists, and Italian Warehousemen, &c.

Goodall's Egg Powder

The most valuable preparation in the world. Universally acknowledged to be the only real substitute for eggs yet discovered. This truly wonderful Powder has not gained its high reputation without meriting it to the fullest extent; its action on Cakes, Puddings, &c., &c., resembles that of the egg in every particular, enriching them in colour and flavour; also rendering them most wholesome and nutritious. Those who have not given it a trial should do so at once; they will find that one penny packet will go as far as four eggs, and one sixpenny tin as far as twenty-eight, thus making the cost one-fourth that of eggs. Sold everywhere, in 1d. packets; 6d. and 1s. tins. By Grocers, Oilmen, Chemists, Italian Warehousemen, Ship Store Dealers, &c.

VEGETABLE ASH MANURE,

RECOMMENDED FOR

TEA, COFFEE, AND INDIGO.

Manufactured from the Ashes of Cow-dung, Horse-dung, &c., supplemented by Bone-dust and Potash Salt.

It is essentially a nourishing, not a forcing Manure.

The manure has been greatly improved by the successful separation of most of the useless matter and, as now manufactured contains :—

30 per cent. of soluble Alkalies (Chloride of Potassium and Sodium, and Sulphate of Potash).
20 „ Lime and Magnesia.
7 „ Phosphoric Acid, equal to 15 per cent. of Phosphate of Lime.

The remainder being Sulphuric Acid, Iron, Carbonic Acid, organic nitrogenous matter and Silica.

The manufacturers are indebted to Messrs. Gillanders, Arbuthnot & Co. for the following Extract from the Fortnightly Report of the Manager "Burkhola Tea Estate," dated 2nd October 1878.

MANURE EXPERIMENTS.

TWO PLOTS, OF 2,793 TEA BUSHES, EACH YIELDED LEAF.

	Vegetable Ash Manure.	*No Manure.*
" *Up to date of last Report* ...	1,414lb.	1,096lb.
" *During the fortnight under Report* ...	260lb.	195lb.
" *Total up to date* ...	1,674lb.	1,291lb."

That is 30 per cent. increase in favour of the manured portion.

The manure was applied in March last, at the rate of 10 cwts. per acre, and can scarcely be said to have exerted its full influence as yet.

The Manager, "Mulla Kuttyoor Tea Concern" writes, under date September 19th, 1878, to Messrs. Begg, Dunlop & Co:—

" *The Vegetable Ash Manure I got up from you as a sample, I have tried on some sickly bushes, and its effect has certainly been beneficial.*"

Sold in strong bags, ready for shipment, at Rs. 50 per ton, inclusive of bags.

A still further concentrated manure, containing 40 *per cent. of soluble Alkalies* and, additionally, 2 to 2½ per cent. of Nitrogen, specially suited for Coffee, at Rs. 65 per ton.

Delivery at the Godowns of the undersigned.

THE

CALCUTTA MUSICAL ESTABLISHMENT,

No. 13/1, Government-place, East.

(LATE BUKINYOUNG & CO.)

FOUNDED, A.D. 1814.

PROPRIETOR—CHARLES GOULD.

THE SMITH AMERICAN ORGAN,

Wholly new designs and effective combinations in Reed Organs.

THE American Organ has been, and still is, the most popular and valued instrument for Churches and Chapels. Immense numbers of them are used in public worship, and it has been found that no other Reed Organs have so much sustaining power joined with such melodious quality of tone.

Style No. 10, *Seven Stops.*

This Style is furnished with two complete sets of reeds of five Octaves. Each set is divided and has a separate stop, for the upper and lower half. The upper half of the first set of reeds is named Flute, and the lower half Principal. In the second set the upper half is named Dulciana, and the lower Diapason. The first set is an Octave higher in pitch than the second, so that the instrument has practically a compass of six Octaves. By having the sets divided, it will be seen that more effect can be produced. The remaining stops are Tremolo, Diapason Forte, and Principal Forte. [*Net Cash, Rs.* 400.

Style No. 16, *Ten Stops.*

This instrument has two-and-a-half sets of reeds, and an Octave of Sub-bass. It has ten stops, *viz.*, Diapason, Dulciana, Flute, Principal Kulophon, Sub-bass, Tremelo, Principal Forte, Diapason Forte, and Octave Coupler. The last stop doubles the power of the Organ, and with the aid of the Sub-bass renders it a powerful and effective instrument for Churches and Halls; at the same time its power is not obtained at any sacrifice of delicacy, and it will be found a most desirable instrument for home use. [*Net Cash, Rs.* 650.

Style No. 20, *Nine Stops.*

This instrument has three complete sets of reeds. Two of the sets are like those in the preceding Styles, having the Principal and Forte Diapason and Dulciana stops. The third set is new and distinct in quality, the upper half is named "Aulodia" and the lower half "Fagotte." The tones of this set are unrivalled in clearness, smoothness, and tender beauty, and their effects in connection with the swell are surprising.

This Organ is one that will be approved by all persons of refined taste. [*Net Cash, Rs.* 750.

N. B.—The above prices are exclusive of packing charges.

The following are some of the advantages of W. & A. Gilbeys system of business :—

VALUE.—The extent of W & A. Gilbey's purchases enables them to give the best value to the public. The duty payments shew that a twentieth part of the Foreign Wines consumed in the United Kingdom is supplied from their Stock.

QUALITY.—Quality is guaranted by W. & A. Gilbey, and is the same whether the Wines and Spirits are obtained direct from their head Establishment or from any of their Agents. The purity and genuineness of all the above Wines are guaranteed in accordance with Act of Parliament 38 and 39 Vic. Capt. 63.

MEASURE.—W. & A. Gilbey have always adhered to the standard of bottle measure recently recognised by Government, *viz* —

6 bottles contain One Gallon; 12 half-bottles contain One Gallon.

TERMS.—Cash to new Constituents; 30 days to known and approved Constituents. Every article not approved of received back after 24 hours.

PUBLISHED IN LONDON.

THE STATESMAN.

A new weekly paper devoted to the discussion of political questions, and especially to a consideration of the economic and administrative reforms called for by the present condition of India, and our relations with that Empire. The Journal is a high class periodical, published in London, in close correspondence with the* STATESMAN AND FRIEND OF INDIA *in Calcutta.

THERE are many cogent reasons why such a paper, as we propose to establish, should receive the support of our countrymen at home. When the Government of India was transferred from the Court of Directors to the Crown, it was inevitable that, sooner or later, the initiative in policy and legislation should also be changed from Calcutta to London. The effects of this transfer are, that the authorities in India are relieved from responsibility to even such feeble public opinion as there exists, while from the ignorance and indifference at Home, the Indian Government in London becomes more despotic than ever. A Government which rules India from Calcutta cannot entirely close its eyes and ears to the effect of its measures upon the people; but an irresponsible Bureaucracy attempting to govern India from Downing-street, legislates in the dark. It can know nothing of the wants of the people, except what is to be gathered from official reports, prepared so as to suit its wishes. The only way to correct this evil, is to raise up in England an enlightened interest in India, by making known, from free and unbiassed sources of information, the veritable state of the country and the character of the administration. In order to do this effectually, it is essential that the London journal should have its roots, so to speak in India. For Western ideas are a solvent of tremendous power; and under their influence, India is changing with a rapidity which must be watched to be understood. It results from this, that an English journal desiring to disseminate the truth regarding India, must obtain its information fresh and fresh, from writers in immediate contact with the facts, convictions, wishes, and aspirations which they delineate. By the establishment of London *Statesman*, in direct connection with a *Statesman* in Calcutta, this object would be accomplished.

Again, all history bears testimony to the fact, that a Government not exposed to the bracing atmosphere of free criticism, becomes corrupt and inefficient. Among Englishmen at least, this may be assumed as a political axiom. We should all of us feel, that if personal rule were set up in England, the national greatness and prosperity would swiftly wither and be lost. And yet, by a curious inconsistency, it is by means of personal irresponsible rule, that we have thought to secure the prosperity of India, and the happiness of its people. This political miracle has not come to pass. Englishmen entrusted with despotic power have too often succumbed to its corrupting influences. They have learned to believe that in *their* case might was right, that because they were entrusted with a mission to elevate and improve the people of India, they might, in their dealings with that people, dispense with those moral laws without which no elevation of character is possible. Everything was to be done *for* the people; nothing was to be done *by* the people. And the consequence has been, that the people of India have been treated by us as a *corpus vile*, on which administrative theorists and crotchet-mongers had full power to experiment as they pleased. There has been neither continuity of principle, nor consistent purpose in our administration, but a series of vast experiments, precipitate in their inception, and disastrous in their consequences. Thus it is that at the close of a century of British rule, carried on to a ceaseless chorus of self-congratulation, we find these singular effects.—A profound gulf existing between rulers and ruled; a peasantry sunk in poverty and indebtedness, and swept away in millions by periodical famines; an army, the most costly in the world, and yet so deficient in organisation that we cannot, in three months, collect 30,000 men on our own frontier; a heavy public debt, an increasing expenditure, and the Empire on the very verge of bankruptcy. We do not say that this comprises the whole of the picture, or that there are not brighter scenes to be found in it. But this we do say, that the above facts are strictly true, and the demand that we should cease from contemplating Narcissus-like, our own perfections, and try to ascertain how and why we have so grievously failed. But this again is impossible, unless a clearer and more accurate knowledge of India is generated in England than at present prevails there.

Lastly, each succeeding year exhibits more clearly that the entire Foreign policy of Great Britain revolves round our Indian Empire Peace or war in the mother country depends upon the opinions formed by the Government of the day, as to the degree of peril which menaces India from this or that Power. At this very time we are engaged in a war, the injustice and cowardice of which are patent, because Lord Beaconsfield and his colleagues think that something must be done to check the progress of Russia in Central Asia. Urged onward by this vague desire to do something, they estrange the Amir Shere Ali by persistently menacing his independence; and then make that estrangement the justification for carrying their menaces into execution. Even assuming that Englishmen were willing to overlook the profligacy of such a policy, they cannot afford to treat it with indifference. For is certain that the costs of an occupation of Afghanistan will have to be defrayed by them. The "scientific frontier" is a meaningless absurdity. If we annex any portion of Afghanistan, we shall be compelled, at no distant date, to annex the whole. It is absolutely certain that India will not be able to furnish the funds for such an acquisition; and the burden must therefore fall upon Great Britain. Are the British tax-payers willing to pay ten millions a year for the doubtful advantage of a "scientific frontier?" Eighteen months ago the Calcutta *Statesman* detected the designs of Lord Beaconsfield's Government, and warned its readers of what was coming. But in Indian official circles its warnings were unheeded, and in England unheard. Had there been in London such an organ of information regarding India, it is well-nigh certain that the present war would have been averted. For at every step the misrepresentations of Government would have been brushed aside, and their veritable policy laid bare; a healthy and enlightened public opinion would have had time to form; and Lord Beaconsfield's policy of "surprising" the country into a war would have been rendered impossible.

But though India will be our speciality, the paper we establish will not be exclusively Indian, but will deal with the whole range of English Politics, domestic as well as foreign, insular as well as Imperial. Social questions and current literature will also receive their due share of regard therein. What we aim at is a high class Liberal paper, interested in all matters in which the nation at large is interested, discussing them in the light of advanced Liberal principles, and accepting of the expression of our policy, the old Liberal sentiment—"The cause of Civil and Religious Liberty all over the world."

The idea is to establish a weekly organ of advanced Liberalism conducted by earnest Christian gentlemen whose interest in Indian affairs is paramount by the circumstance of their connection with the country, and exact knowledge of its affairs and administration. It will contain a weekly summary of the latest news from all the Indian papers, brought down to date by the latest telegraphic advices, and reviewed in their light. There is no such paper now, and the conception is believed to be a sound one. Our hope is to awaken by means of the paper, a deeper interest in India, and a higher sense of our responsibilities as its rulers, than unhappily at present exists; and to do this by floating Indian affairs into public notice, on the strength of the Imperial and domestic interests which they so vitally effect.

Subscriptions in advance, including postage to India, Rs. 15 a year.

Prices and particulars on application.

PHŒNIX IRON WORKS,

CALCUTTA.

THE OLDEST ENGINEERING ESTABLISHMENT IN INDIA.

JESSOP & CO.,

Civil and Mechanical Engineers, Contractors, Brass and Iron Founders, Metal Merchants, &c.
Forged and Cast Iron Work, Boilers, Machinery for Jute, Cotton, and Rice Mills, Collieries, Indigo Concerns, Tea Gardens, &c., Contractors and Brick-making Plant, and every class of Iron and Brass Work made to order.

SOLE AGENTS FOR

Robey & Co.'s celebrated Portable and Fixed Engines and Machinery, Gwynne & Co.'s Centrifugal Pumps, Gould's Rotary Pumps, and Robinson's Patent Steam Traps.

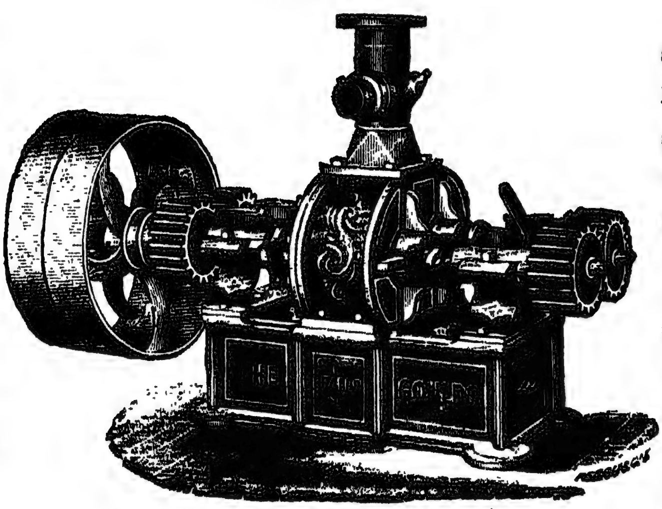
Importers and Manufacturers of every description of Steam Engines and Machinery.

Robey & Co.'s Portable, Horizontal Fixed, and Patent "Robey" Semi-fixed Engines, Combined Vertical Engines and Boilers, Land and Marine Boilers, Gould's Rotary Power Pumps, Hand Lift and Force Pumps, Gwynne's Centrifugal Pumps, Tangye's "Special" Steam Pump, "Vauxhall" Donkey Pumps, Flour Mills, Soorkee Mills, Pug Mills, Brick-making Machines, Road Rollers, Saw Benches, Stoney's Patent Soorkee Screwing Machines and Double Acting Helical Excavators, Slide Surfacing and Screw Cutting Lathes, Drilling Machines, Punching and Shearing, Slotting and Screwing Machines, Emery Grinding Machines, Spencer's Hand Drilling Machines, Chaff Cutting Machines, Kennedy's Patent Bar Shears, Selkirk's Boiler Tube Beaders, Steam Pressure Recorders, Electric Pens, Richard's Engine Indicators, Gifford's Injectors, Cooking Stoves, Fire Proof Safes.

No. 3 Pump, has a 3 inch suction pipe, throws a 2½-inch stream, and with 175 revolutions discharges 175 gallons per minute.

No. 4 Pump, has a 5-inch suction pipe, throws a 4-inch stream, and with 200 revolutions discharges 325 gallons per minute.

No. 5 Pump, has a 6-inch suction pipe, throws a 5-inch stream, and with 200 revolutions discharges 500 gallons per minute.



The mandrels of these Pumps are made of cast-steel with Babbet's metal boxes, and there are no valves or leather packing, which renders them very durable and not likely to get out of order. The great advantage of these over the ordinary Centrifugal Pumps is that they will draw water running at any rate of speed, but of course the higher the speed at which they are driven the greater the discharge obtained.

GOULD'S ROTARY PUMP.

INDIGO AND TEA PLANTERS' IMPLEMENTS AND STORES.

Indigo Screws, Indigo Beaters, Indigo Pans, Indigo Pumps, Howard's Patent D and Turnwrest Ploughs, Kodallies, Pruning and Budding Knives, Grubbing Hoes, Assam Daws and Forks, Bill Hooks, American Felling Axes, Scissors, Shears, Saws, Mowing Machines, Tea Sieves, Tea Lead Solder, Galvanized Netting, Iron and Brass Wire Gauze, Leather and India-rubber Belting, Tool Chests, Grindstones, India-rubber Suction and Delivery Hose, Canvas Hose, French Wire and other Nails, Hoop Iron, Platform Weighing Machines, Spring Balances, Gram and Oat Crushing Machines, Maximum and Minimum Thermometers, Steel Band Chains for land measuring.

ENGINEERS' TOOLS AND STORES OF ALL KINDS.

Duplex Punches, Boiler Bears, Lifting Jacks, Stocks and Dies, Ratchet Braces, Tube Expanders and Cutters, Engine, Spindle, and Small Machine Counters, Vacuum and Pressure Gauges, Hydraulic Gauges, Boiler Tubes, Steam and Hydraulic Piping, Boiler Cocks and Fittings, Triple Acting Ratchet Braces, Horse Power Computing Scales, Angular Bit Stocks, Stephen's American Parallel Vices, Adjustable Clamps, Adjustable Iron Block Planes, Cranes, Vegetable Oil, "Climax" Pipe Wrenches, Box Scrapers, Patent Glass Cutters, Boiler Rivets, Bolts and Nuts, Coach and Wood Screws, &c., &c.

McRAE'S PATENT SUB-SOIL AND GENERAL PLOUGH.

This plough, of which we have been appointed sole manufacturers by the Patentee, is comparatively light and cheap, and stirs up the soil to three times the depth of a native Plough, and for a breadth of at least seven inches, leaving the good mould on the top. Particulars and prices on application.

Always on hand a large stock of Plate, Bar, Angle, Tee and Corrugated Iron, Steel, Brass, Copper, Pig Iron, Foundry Coke, Smithy Coal, Fire Bricks, and Fire Clay.

BIRD & CO.,

MANUFACTURERS OF THE

PATENT IMPROVED LEATHER—

OIL-PROOF, WATER-PROOF, IMPERISHABLE.

WORKS:–

LIME-HOUSE, LONDON, E.

THIS Leather is submitted to a patent process, rendering it stronger, more durable, and impervious to damp and heat. Being waterproof, it is particularly adapted to work in wet and exposed situations, and in the hot and moist atmosphere of the Tropics.

THE BANDS

Will stretch less than those made of ordinary leather, thus saving both the time and trouble so frequently expended in taking up belting; while for agricultural purposes, where the Bands have to remain in the open, this Leather will be found invaluable.

THE HOSE PIPING.

Besides being stronger than ordinary hose, never becomes hard, requires no oiling or dressing, and after being used, can be put away until next wanted without any further care or labour being bestowed upon it.

THE BUCKETS

Are handsomer, stronger, and lighter, and will last longer than those made of wood or iron.

THE HARNESS

Will bear exposure to the heaviest rain, only requires to be wiped with a dry cloth; neither oiling nor dressing is wanted. The leather, which is particularly recommended for Cart and Heavy Harness, though equally valuable for lighter purposes, such as Carriage Hoods, Aprons, &c.

BOOT AND SHOE PURPOSES.

The Soles and Clumps are perfectly impervious to rain and snow water, and keep the feet warm and dry in the coldest or wettest weather. Uppers can also be made waterproof.

ARMY PURPOSES.

This Patent Leather will be found most valuable and economical in the various departments of the Army, retaining its specific properties until worn out, and requiring but little care and attention; the saving in time and money, in Artillery harness alone will be great. This Leather will be found particularly adapted for use in India and all tropical climates, where the great heat and moisture prove so destructive to ordinary Leather.

GENERAL PURPOSES.

There are of course numberless other purposes to which this Leather can be applied, at, viz :—Pump Leathers, Portmanteaus, Bags, Gun Cases Cartridge Boxes, Belts, Straps, &c., &c., and any information required can be obtained on application at the Works, Limehouse, London, E.

ST. PAUL'S COLLEGE is intended to supply a public School education at a moderate cost. The teaching is strictly in accordance with the principles of the Church of England.

Boys are prepared for the Universities, for Woolwich, and other competitive examinations, and, if required, for Mercantile pursuits. The inclusive charge for Board and Tuition, Washing, Medical Attendance, &c., is sixty Guineas a year.

Pupils received in January, April, and September. All applications should be made to the Warden or Sub-Warden.

A LADY and Gentleman residing near London, are willing to undertake the charge of two or three young children. Every care would be taken, a superior education imparted, and the comforts of a happy Christian home provided.

The highest references will be furnished.

Applications for further particulars and terms should be addressed South Norwood, care of D. J. Keymer & Co., 1, Whitefriar's-street, London, E.C.

A LADY of the Church of England, who resides in a sheltered Home, receives 3 or 4 young children from 3 to 10 years of age to be educated with her own little ones. They receive a Mother's care, with Educational Rudiments in English, French, Latin, Music, Singing, and Drawing. Horse or Carriage exercise can be had if required for delicate children. Terms from 33 Guineas per annum according to requirements.

Photo of Residence and references from Clergymen and Parents of children can be had on application. Address, Mrs. John Allen Smith, Meon Hall, Chipping Campden, Gloucestershire.

SITUATIONS VACANT AND WANTED.

6 lines ... ... £ 0 5 0

And 9*d*. per line for every additional line—Average 11 words to a line.

TO INVESTORS.

AN excellent opportunity occurs for securing a Half Share in a well-established Tea Estate, situated in a most healthy part of the Neilgherries, and only 30 hours by cart and rail from the nearest seaport. Labour and Fuel are both abundant in the neighbourhood.

The Estate which is upwards of one hundred acres in extent, comprises a large well-built house with stables and offices complete, factories, &c., with machinery worked by water power. About seventy-two per cent. of the acreage is under tea, more than half of which is in full bearing. There are besides about twenty thousand Gum and some Cinchona trees on the plantation. Price of Half Share, £2,750 Sterling.

N.B.—The refusal of the other half share could probably be arranged for if desired.

For further particulars, apply to Nicholls & Co., 8, Old Court House-street, Calcutta; or 1, Whitefriar's-street, Fleet-street, London, E. C.

FLAX.

A GENTLEMAN experienced in the cultivation and preparation of flax, is open to an engagement during the ensuing season.

Apply to FLAX, care of J. M. J., 10, Jackson's Ghât-street, Calcutta.

BANKS, &c.

ROYAL INSURANCE COMPANY.

The Annual Meeting of the Company was held August 1st, 1879.

LIFE DEPARTMENT.

THE total Income from Premiums in 1878 amounted to £246,514, and Interest on Investments to £90,248. The Claims by Death and Matured Policies were £153,841. After payments of all claims and expenses, £143,104 has been added to the Life Funds, which now amount to £2,389,907.

The Funds of the Company now stands as follows:—

Capital paid up ...	£289,545	0	0
Fire Fund	500,000	0	0
Reserve Fund	00,000	0	0
Balance, Profit and Loss	69,707	11	0
Life Fund	2,389,907	3	11
Total Funds in hand ...	£4,049,159	14	11

MEDICINES.

Prices 1s. 1½. 2s. 3d. 4s. 6d. and 11s per bottle.

TIC-SANO

The Great Vegetable Remedy

FOR

GOUT, RHEUMATISM, NEURALGIA, SCIATICA,

LUMBAGO, NERVOUS

AND

SICK HEADACHE.

TIC SANO not only gives immediate relief, but also acts as a stimulating Tonic, imparting a healthy tone to the digestive organs, and purifies the blood by throwing off all morbid humours through the skin. It is a vegetable compound, which can be taken with safety by persons of the most delicate constitution. Thousands of sufferers have testified to its marvellous efficacy.

The Proprietors of TIC SANO are in a position to state positively that it has cured where every other remedy had failed to give the slightest relief.

A chemist writes :—" Every person who has had one bottle, has called for another."

JOYCE & CO.,
25, OLD JEWRY, LONDON.

"FOR THE BLOOD IS THE LIFE."

CLARKE'S
"WORLD-FAMED BLOOD MIXTURE."

TRADE MARK

"BLOOD MIXTURE."

THE GREAT BLOOD PURIFIER AND RESTORER,

FOR cleansing and clearing the blood from all impurities, cannot be too highly recommended.

For Scrofula, Scurvy, Skin Diseases, and Sores of all kinds it is a never-failing and permanent cure.

It

Cures old Sores.
Cures Ulcerated Sores on the Neck.
Cures Ulcerated Sore Legs.
Cures Blackheads, or Pimples on the Face.
Cures Scurvy Sores.
Cures Cancerous Ulcers.
Cures Blood and Skin Diseases.
Cures Glandular Swellings.
Clears the Blood from all impure Matter, from whatever cause arising.

As this mixture is pleasant to the taste, and warranted free from any thing injurious to the most delicate constitution of either sex, the Proprietor solicits sufferers to give it a trial to test its value.

Thousands of Testimonials from all parts.

Sold in Bottles 2s. 6d, each, and in cases, containing six times the quantity, 11s. each—sufficient to effect a permanent cure in the great majority of long-standing cases, BY ALL CHEMISTS and PATENT MEDICINE VENDORS throughout the world.

Sole Proprietor, F. J. CLARKE, Chemist.

Branch Offices: { **KING-STREET HALL, BRISTOL.**
42, GEORGE-STREET PLYMOUTH.

WORKS:

Victoria Docks, London; & Cattledown, Plymouth.

VEGETABLE ASH MANURE,

RECOMMENDED FOR

TEA, COFFEE, AND INDIGO,

Manufactured from the Ashes of Cow-dung, Horse-dung, &c., supplemented by Bone-dust and Potash Salt.

It is essentially a nourishing, not a forcing Manure.

The manure has been greatly improved by the successful separation of most of the useless matter and, as now manufactured contains :—

30 per cent. of soluble Alkalies (Chloride of Potassium and Sodium, and Sulphate of Potash).
20 „ Lime and Magnesia.
7 „ Phosphoric Acid, equal to 15 per cent. of Phosphate of Lime.

The remainder being Sulphuric Acid, Iron, Carbonic Acid, organic nitrogenous matter and Silica.

The manufacturers are indebted to Messrs. Gillanders, Arbuthnot & Co. for the following Extract from the Fortnightly Report of the Manager "Burkhola Tea Estate," dated 2nd October 1878.

MANURE EXPERIMENTS.

TWO PLOTS, OF 2,793 TEA BUSHES, EACH YIELDED LEAF.

	Vegetable Ash Manure.	No Manure.
"Up to date of last Report	1,414lb.	1,096lb.
"During the fortnight under Report	260lb.	195lb.
"Total up to date	1,674lb.	1,291lb."

That is 30 per cent. increase in favour of the manured portion.

The manure was applied in March last, at the rate of 10 cwts. per acre, and can scarcely be said to have exerted its full influence as yet.

The Manager, "Mulla Kuttyoor Tea Concern" writes, under date September 19th, 1878, to Messrs. Begg, Dunlop & Co:—

"*The Vegetable Ash Manure I got up from you as a sample, I have tried on some sickly bushes, and its effect has certainly been beneficial.*"

Sold in strong bags, ready for shipment, at Rs. 50 per ton, inclusive of bags.

A still further concentrated manure, containing 40 *per cent. of soluble Alkalies* and, additionally, 2 to 2½ per cent. of Nitrogen, specially suited for Coffee, at Rs. 65 per ton.

Delivery at the Godowns of the undersigned.

BEGG, DUNLOP & CO.,

Sole Agents.

PUBLISHED IN LONDON.

THE STATESMAN.

A new weekly paper devoted to the discussion of political questions, and especially to a consideration of the economic and administrative reforms called for by the present condition of India, and our relations with that Empire. The Journal is a high class periodical, published in London, in close correspondence with the STATESMAN AND FRIEND OF INDIA *in Calcutta.*

THERE are many cogent reasons why such a paper, as we propose to establish, should receive the support of our countrymen at home. When the Government of India was transferred from the Court of Directors to the Crown, it was inevitable that, sooner or later, the initiative in policy and legislation should also be changed from Calcutta to London. The effects of this transfer are, that the authorities in India are relieved from responsibility to even such feeble public opinion as there exists, while from the ignorance and indifference at Home, the Indian Government in London becomes more despotic than ever. A Government which rules India from Calcutta cannot entirely close its eyes and ears to the effect of its measures upon the people; but an irresponsible Bureaucracy attempting to govern India from Downing-street, legislates in the dark. It can know nothing of the wants of the people, except what is to be gathered from official reports, prepared so as to suit its wishes. The only way to correct this evil, is to raise up in England an enlightened interest in India, by making known, from free and unbiassed sources of information, the veritable state of the country and the character of the administration. In order to do this effectually, it is essential that the London journal should have its roots, so to speak in India. For Western ideas are a solvent of tremendous power; and under their influence, India is changing with a rapidity which must be watched to be understood. It results from this, that an English journal desiring to disseminate the truth regarding India, must obtain its information fresh and fresh, from writers in immediate contact with the facts, convictions, wishes, and aspirations which they delineate. By the establishment of London *Statesman*, in direct connection with a *Statesman* in Calcutta, this object would be accomplished.

Again, all history bears testimony to the fact, that a Government not exposed to the bracing atmosphere of free criticism, becomes corrupt and inefficient. Among Englishmen at least, this may be assumed as a political axiom. We should all of us feel, that if personal rule were set up in England, the national greatness and prosperity would swiftly wither and be lost. And yet, by a curious inconsistency, it is by means of personal irresponsible rule, that we have thought to secure the prosperity of India, and the happiness of its people. This political miracle has not come to pass. Englishmen entrusted with despotic power have too often succumbed to its corrupting influences. They have learned to believe that in *their* case might was right, that because they were entrusted with a mission to elevate and improve the people of India, they might, in their dealings with that people, dispense with those moral laws without which no elevation of character is possible. Everything was to be done *for* the people; nothing was to be done *by* the people. And the consequence has been, that the people of India have been treated by us as a *corpus vile*, on which administrative theorists and crotchet-mongers had full power to experiment as they pleased. There has been neither continuity of principle, nor consistent purpose in our administration, but a series of vast experiments, precipitate in their inception, and disastrous in their consequences. Thus it is that at the close of a century of British rule, carried on to a ceaseless chorus of self-congratulation, we find these singular effects:—A profound gulf existing between rulers and ruled; a peasantry sunk in poverty and indebtedness, and swept away in millions by periodical famines; an army, the most costly in the world, and yet so deficient in organisation that we cannot, in three months, collect 30,000 men on our own frontier; a heavy public debt, an increasing expenditure, and the Empire on the very verge of bankruptcy. We do not say that this comprises the whole of the picture, or that there are not brighter scenes to be found in it. But this we do say, that the above facts are strictly true, and the demand that we should cease from contemplating Narcissus-like, our own perfections, and try to ascertain how and why we have so grievously failed. But this again is impossible, unless a clearer and more accurate knowledge of India is generated in England than at present prevails there.

Lastly, each succeeding year exhibits more clearly that the entire Foreign policy of Great Britain revolves round our Indian Empire Peace or war in the mother country depends upon the opinions formed by the Government of the day, as to the degree of peril which menaces India from this or that Power. At this very time we are engaged in a war, the injustice and cowardice of which are patent, because Lord Beaconsfield and his colleagues think that something must be done to check the progress of Russia in Central Asia. Urged onward by this vague desire to do something, they estrange the Amir Shere Ali by persistently menacing his independence; and then make that estrangement the justification for carrying their menaces into execution. Even assuming that Englishmen were willing to overlook the profligacy of such a policy, they cannot afford to treat it with indifference. For it is certain that the costs of an occupation of Afghanistan will have to be defrayed by them. The "scientific frontier" is a meaningless absurdity. If we annex any portion of Afghanistan, we shall be compelled, at no distant date, to annex the whole. It is absolutely certain that India will not be able to furnish the funds for such an acquisition; and the burden must therefore fall upon Great Britain. Are the British tax-payers willing to pay ten millions a year for the doubtful advantage of a "scientific frontier?" Eighteen months ago the Calcutta *Statesman* detected the designs of Lord Beaconsfield's Government, and warned its readers of what was coming. But in Indian official circles its warnings were unheeded, and in England unheard. Had there been in London such an organ of information regarding India, it is well-nigh certain that the present war would have been averted. For at every step the misrepresentations of Government would have been brushed aside, and their veritable policy laid bare; a healthy and enlightened public opinion would have had time to form; and Lord Beaconsfield's policy of "surprising" the country into a war would have been rendered impossible.

But though India will be our speciality, the paper we establish will not be exclusively Indian, but will deal with the whole range of English Politics, domestic as well as foreign, insular as well as Imperial. Social questions and current literature will also receive their due share of regard therein. What we aim at is a high class Liberal paper, interested in all matters in which the nation at large is interested, discussing them in the light of advanced Liberal principles, and accepting of the expression of our policy, the old Liberal sentiment—"The cause of Civil and Religious Liberty all over the world."

The idea is to establish a weekly organ of advanced Liberalism conducted by earnest Christian gentlemen whose interest in Indian affairs is paramount by the circumstance of their connection with the country, and exact knowledge of its affairs and administration. It will contain a weekly summary of the latest news from all the Indian papers, brought down to date by the latest telegraphic advices, and reviewed in their light. There is no such paper now, and the conception is believed to be a sound one. Our hope is to awaken by means of the paper, a deeper interest in India, and a higher sense of our responsibilities as its rulers, than unhappily at present exists; and to do this by floating Indian affairs into public notice, on the strength of the Imperial and domestic interests which they so vitally effect.

SEVEN PRIZE MEDALS awarded to GOODALL'S HOUSEHOLD SPECIALITIES. A single trial solicited from those who have not yet tried those preparations.

Goodall's Yorkshire Relish

THE most delicious sauce in the world; enriches hot joints, stews, chops, fish, &c.; with soup it is charming, blends admirably with all gravies; makes cold meat a luxury; makes the plainest viands palatable; the daintiest dishes more delicious; a great addition to cheese; every dish is improved by its addition; epicures pronounce it the best sauce; beware of colourable imitations.

CAUTION.—It having come to our knowledge that an imitation of our celebrated Sauce, the Yorkshire Relish, is being palmed upon purchasers, we beg that they will insist upon having the only genuine Yorkshire Relish, bearing a label with the Trade Mark, a "Willow Pattern Plate," and our name, "GOODALL, BACKHOUSE and Co., LEEDS," with a protecting label over the stopper. We are sorry that respectable tradesmen should lend themselves to such an imposture for the sake of a little extra profit. Sold by Grocers, Oilmen, Chemists, &c., in bottles, 6d., 1s., and 2s. each.

Goodall's Baking Powder

AWARDED Seven Prize Medals for superior quality. The best in the world. Defies comparison. Makes delicious puddings without eggs, pastry without butter, and beautiful light bread without yeast. One trial will convince the most sceptical of its superiority over others.

Sold by Grocers, Oilmen and Chemists, &c., in 1d. packets, 6d., 1s., 2s., and 5s. tins.

Goodall's Custard Powder

FOR making delicious custards without eggs, in less time and at half the price. Delicious to plum pudding and jam tarts; delicious to stewed rice and all kinds of fruit; delicious to everything; delicious alone.

Give it a trial.—Sold in boxes, 6d. and 1s. each, by Grocers, Chemists, Italian Warehousemen, &c.

Goodall's Egg Powder

ACKNOWLEDGED to be the only real substitute for eggs yet discovered; its action on Cakes, Puddings, &c., &c., resembles that of the egg in every particular, enriching them in colour and flavour, rendering them most wholesome and nutritious. One penny packet will go as far as four eggs! and one sixpenny tin as far as twenty-eight!

Sold everywhere, in 1d. Packets; 6d. and 1s. Tins.

Goodall's Ginger Beer Powder

MAKES three gallons of the best Ginger Beer in the world for threepence. Invaluable for producing a delicious and invigorating beverage, possessing valuable medicinal properties, thereby rendering it the most wholesome and perfect beverage ever discovered for both winter and summer use, is easily made, and acknowledged the best and cheapest.

Sold in packets, 3d. and 6d. each, by all Grocers, Chemists, and Italian Warehousemen, &c.

Goodall's Quinine Wine

IS invaluable for indigestion nervousness, gout, rheumatics, &c. A wineglassful twice or thrice a day will be found both grateful and efficacious in all cases in which a cordial tonic is required, far superior to sherry and bitters or bitter beer.

Sold by Chemists, Grocers, &c., at 2s. per bottle.

Goodall's Mushroom Ketchup

CONFIDENTLY recommended to all true lovers of the Pure Mushroom. Prepared by a special Steam process, from the PURE JUICE, producing a FULL AND RICH FLAVOURED KETCHUP, unrivalled for its GREAT STRENGTH! PERFECT PURITY!! and UNSURPASSED FLAVOUR!!!

Sold in bottles at 6d., 1s., and 2s. each, by Grocers, Oilmen, and Italian Warehousemen all over the kingdom.

Goodall's Brunswick Black

FOR Painting Stoves, Grates, Iron, Tin, &c. This invaluable composition is superior to any yet offered to the public, possessing great brilliancy and thoroughly protecting the articles it is applied to.

Sold in bottles at 6d. and 1s. each by Grocers, Oilmen, Chemists, Italian Warehousemen, Ship Store Dealers, &c. Shippers and the Trade supplied by the Sole Proprietors,

GOODALL, BACKHOUSE, & CO., White Horse Street, Leeds, ENGLAND.

WINES, &c.

INTRODUCED BY

W. & A. GILBEY'S

SPARKLING "BRUT SAUMUR" CHAMPAGNE

FROM

FRANCE.

FIRST SHIPMENT TO THIS COUNTRY.

Castle "Brut Saumur,"

Is the produce of selected grapes grown in the extensive wine districts of Saumur, an invaluable sparkling wine to those who require wines free from all saccharine. It is strictly what is known as a "Brut" or "Natural" wine, that is to say, no saccharine has been added since the completion of the fermentation.

	Rs.
Quarts per dozen	28
Pints " "	30

Dr. Druitt writing in the *Medical Times and Gazette* of the 29th March 1879, states as follows :—

"Added to the practical experience of the last dozen years "during which I have known these wines, I may give "the following theoretical reasons for the superiority of "'*Vin Brut*,' as a stimulant in many cases, more particu- "larly dyspeptic, and others where the consumption of "sugar should be avoided.

"*First.*—The Brut wine is STOUTER and MORE GENEROUS.

"*Second.*—It is more APPETITE-COMPELLING.

"*Thirdly.*—The extra degorgement and the absence of dosage "with Sugar and Brandy render "Brut Saumur" less liable "to disagree while it meets for INVALIDS A WANT THAT HAS LONG "BEEN FELT by the Medical profession, but which perhaps "previously has not been within general grasp (*viz.*) that of "a PURE, SPARKLING, and MODERATELY STIMULATING BEVERAGE "at a reasonable price. The man in perfect health may "drink which he likes best, without fear of the small "quantity of sugar in the ordinary wine, but if he prefers "a dryer wine here it is."

The following also is the report of Dr. D. Waldie, F.C.S., after analysis :—

"The results of this (analysis) indicate that the Brut Saumur "is a natural wine, like other NATURAL UNSACCHARATED or "UNFORTIFIED wines, the matter and properties of the consti- "tuents of which have been ascertained, so far as I can "judge, from the analysis, it is a *good, wholesome wine,* "possessing the properties belonging to the BEST NATURAL "WINES, without the peculiarities of certain kinds objection- "able in many cases such as the astringency of Clarets in "the excessive amount of alcohol or sugar in others."

With the opinions of two such well-known authorities both in England and in India, we offer the above wine to our constituents and the public, our stock however is small, the shipment being only a trial one, early application therefore is necessary to prevent disappointment.

THE

CALCUTTA MUSICAL ESTABLISHMENT,

No. 13/1, Government-place, East.

(LATE BURKINYOUNG & CO.)

FOUNDED, A.D. 1814.

PROPRIETOR—CHARLES GOULD.

THE SMITH AMERICAN ORGAN,

Wholly new designs and effective combinations in Reed Organs.

THE American Organ has been, and still is, the most popular and valued instrument for Churches and Chapels. Immense numbers of them are used in public worship, and it has been found that no other Reed Organs have so much sustaining power joined with such melodious quality of tone.

Style No. 10, *Seven Stops.*

This Style is furnished with two complete sets of reeds of five Octaves. Each set is divided and has a separate stop, for the upper and lower half. The upper half of the first set of reeds is named Flute, and the lower half Principal. In the second set the upper half is named Dulciana, and the lower Diapason. The first set is an Octave higher in pitch than the second, so that the instrument has practically a compass of six Octaves. By having the sets divided, it will be seen that more effect can be produced. The remaining stops are Tremelo, Diapason Forte, and Principal Forte. [*Net Cash, Rs.* 400.

Style No. 16, *Ten Stops.*

This instrument has two-and-a-half sets of reeds, and an Octave of Sub-bass. It has ten stops, *viz.,* Diapason, Dulciana, Flute, Principal Kulophon, Sub-bass, Tremelo, Principal Forte, Diapason Forte, and Octave Coupler. The last stop doubles the power of the Organ, and with the aid of the Sub-bass renders it a powerful and effective instrument for Churches and Halls; at the same time its power is not obtained at any sacrifice of delicacy, and it will be found a most desirable instrument for home use. [*Net Cash, Rs.* 650.

Style No. 20, *Nine Stops.*

This instrument has three complete sets of reeds. Two of the sets are like those in the preceding Styles, having the Principal and Forte Diapason and Dulciana stops. The third set is new and distinct in quality, the upper half is named "Aulodia" and the lower half "Fagotte." The tones of this set are unrivalled in clearness, smoothness, and tender beauty, and their effects in connection with the swell are surprising.

This Organ is one that will be approved by all persons of refined taste. [*Net Cash, Rs.* 750.

N.B.—The above prices are exclusive of packing charges.

SEVEN PRIZE MEDALS AWARDED.

GOODALL'S HOUSEHOLD SPECIALITIES.

A Single Trial solicited from those who have not yet tried these splendid preparations.

Goodall's Yorkshire Relish

The most delicious sauce in the world; enriches hot joints, stews, chops, fish, &c.; with soup it is charming; blends admirably with all gravies; makes cold meat a luxury; makes the plainest viands palatable; the daintiest dishes more delicious; a great addition to cheese; every dish is improved by its addition; epicures pronounce it the best sauce; beware of colourable imitations.

CAUTION.—On each label is our Trade Mark, Willow Pattern Plate, and name, GOODALL, BACKHOUSE and Co. No other is genuine.

Whatever prejudice may have existed at any time on account of its cheapness has become entirely dissipated by the daily use of this really good sauce. We merely solicit a trial from those who have not used it, after which we feel confident they will use no other sauce.

Over four million (4,000,000) bottles sold annually. Largest sale of any sauce in the world. Sold by Grocers, Oilmen, Chemists, &c., in bottles, 6d., 1s., and 2s. each.

TESTIMONIAL.—"4, Wimbourne Street, New North Road, London, N., 18th May, 1875.—Gentlemen,—I have not the pleasure of knowing you—never met you, never saw you—but still for a great length of time my sideboard has never lacked your celebrated YORKSHIRE RELISH, and it gives me very great pleasure to forward this Testimonial in its favour, provided you think it worthy of your acceptance. My sedentary habits as a writer for the magazines, &c., very often makes me exceedingly peevish with my meals, but still, no matter what I have, your YORKSHIRE RELISH always brings me to. Sometimes I have a hot joint that it enriches, sometimes cold meat that it makes exceedingly tasty and palatable—with soup it is charming. And sometimes, when the press is waiting for matter, I can make a very good makeshift for dinner with a roll steeped in it; so that in each and every sense of the word I cannot speak too highly of that which I find so good, so useful, and so cheap. If it is likely to be productive of good you are quite at liberty to publish this. Yours truly, the Author of 'Grace Darling,' 'Harriet Stanton,' 'The Wreck of the Royal Charter,' &c.—To Goodall, Backhouse, and Co., Leeds.

Goodall's Quinine Wine

The best tonic for invalids; the cheapest, because the best; invaluable for neuralgia; testimonials to its efficacy innumerable; pre-eminent for purity and strength; recommended by every one who has tried it; thousands benefited by its use; awarded seven prize medals.

Highly recommended by the most eminent physicians, and acknowledged to be the best and cheapest tonic yet introduced. Strengthens the whole system, and stimulates the appetite. It is invaluable for Indigestion, Nervousness, Gout, Rheumatics, &c. Has proved an invaluable and agreeable stomachic to all suffering from general debility and loss of appetite. The best restorative for the weak, young, or aged. Is admirably adapted for delicate children and persons to whom quinine in any other form is objectionable, and is especially suited as a vehicle for the administration of Cod Liver Oil where the combined effect of Quinine and of the *Ol. Jecoris Aselli* is desirable. A wineglassful twice or thrice a day will be found both grateful and efficacious in all cases in which a cordial tonic is required—far superior to sherry and bitters or bitter beer.

[TESTIMONIAL FROM MISS EMILY FAITHFULL.]

"Victoria Press, 85, Praed Street, London, W., 20th August, 1874.

"Dear Sirs,—Having tested your excellent Quinine Wine, I am only too glad to testify to its efficacy in neuralgia, &c., as a certain cure and preventive, which is better than cure.—Yours truly, "EMILY FAITHFULL."

Sold by Grocers, Chemists, Patent Medicine Dealers and Confectioners, in Large Bottles, at 2s. each.

Goodall's Brunswick Black

For painting stoves, grates, iron, tin, &c. This invaluable composition is superior to any yet offered to the public, possessing great brilliancy, and thoroughly protecting the article it is applied to.

Sold in bottles at 6d. and 1s. each.

Goodall's Mushroom Ketchup

This splendid speciality is confidently recommended to all true lovers of the pure mushroom. It is prepared with the utmost care from the PURE JUICE, by a special steam process, secured at great cost by the proprietors, unrivalled for producing a ketchup uniform in strength, with a FULL AND RICH FLAVOR unpossessed by any other preparation of its kind in the market. One trial is sufficient to convince all of its great strength, perfect purity, and unsurpassed flavor.

Sold in bottles at 6d., 1s., and 2s. each, by Grocers, Oilmen, and Italian Warehousemen all over the kingdom.

Goodall's Baking Powder

THE BEST BAKING POWDER IN THE WORLD.

Warranted Pure, Free from Alum, and all other Injurious Ingredients.

AWARDED SEVEN PRIZE MEDALS.	MANUFACTURED FROM THE PUREST INGREDIENTS.
UNRIVALLED for EFFICIENCY and PURITY.	TESTIMONIALS INNUMERABLE.
RECOMMENDED by ALL WHO HAVE TRIED IT.	DISPENSES WITH BREWERS' YEAST.
DEFIES COMPARISON.	GIVE IT A TRIAL.

The cheapest because the best; indispensable to every household; and an inestimable boon to housewives. Makes delicious puddings without eggs, pastry without butter, and beautiful light bread without yeast. One trial will convince the most sceptical of its superiority over others.

[TESTIMONIAL.] "New North Road, London, N., May 4, 1876.

"Gentlemen;—Your Baking Powder is decidedly the best I ever used, and I shall recommend it to all my friends, being positive that it is the VERY BEST. "MARY WILSON, Matron."

Sold everywhere in 1d. Packets, 6d., 1s. 2s., and 5s. Tins, by Grocers, Oilmen, Chemists, &c.

Goodall's Custard Powder

For making delicious Custards, without eggs, in less time and at half the price. Delicious to plum pudding, delicious to jam tarts, delicious to stewed rice, delicious to all kinds of fruit, delicious to all kinds of puddings, delicious to all kinds of fruit pies, delicious to everything, delicious alone. Unequalled for the purposes intended. Will give the utmost satisfaction if the instructions given are implicitly followed. The Proprietors entertain the greatest confidence in the article, and can recommend it to housekeepers generally as a useful agent in the preparation of a good custard. GIVE IT A TRIAL.

Sold in boxes 6d. and 1s. each by Grocers, Chemists, Italian Warehousemen, &c.

[TESTIMONIAL.] "London, 5th February, 1878.

"Gentlemen,—Your Custard Powder is simply delightful, and cannot be approached by any powder I have hitherto used. "Yours respectfully, E. P.

"To Messrs. Goodall, Backhouse, & Co., White Horse Street, Leeds."

Goodall's Ginger Beer Powder

Makes three gallons of the best Ginger Beer in the world for threepence. The most valuable preparation for the production of a delicious and invigorating beverage. This Powder stands unrivalled, possessing valuable medicinal properties to a very large extent. It is not only cooling in its nature, but also an invaluable stomachic, thereby rendering it the most wholesome and perfect beverage ever discovered for both winter and summer. It is easily made, and acknowledged to be by far the cheapest and best Ginger Beer Powder ever offered to the public.

CAUTION.—To prevent disappointment be sure and ask for GOODALL'S GINGER BEER POWDER, as most of the so-called powders are made up of inferior articles, and contain little or no Ginger. Sold in Packets, 3d. and 6d. each, by all Grocers, Chemists, and Italian Warehousemen, &c.

Goodall's Egg Powder

The most valuable preparation in the world. Universally acknowledged to be the only real substitute for eggs yet discovered. This truly wonderful Powder has not gained its high reputation without meriting it to the fullest extent; its action on Cakes, Puddings, &c., &c., resembles that of the egg in every particular, enriching them in colour and flavour; also rendering them most wholesome and nutritious. Those who have not given it a trial should do so at once; they will find that one penny packet will go as far as four eggs, and one sixpenny tin as far as twenty-eight, thus making the cost one-fourth that of eggs. Sold everywhere, in 1d. packets; 6d. and 1s. tins. By Grocers, Oilmen, Chemists, Italian Warehousemen, Ship Store Dealers, &c.

Sole Proprietors and Manufacturers, **Goodall, Backhouse & Co., White Horse St., Leeds, ENGLAND.**

APPLICATIONS.

For the lease or disposal of the Government Tobacco and Experimental Farm at Myouk Toung at Akyab District, will be received by the undersigned.

THE Farm is on the Kaladar river, about 75 miles from Akyab, with which pl. ce there is we kly communication by steam launch.

There are good out-buildings, and about 50 acres of cultivated ground waste land suitable for Tobacco, Tea, Rice, &c., is at once available for the extension of the farm, and may be granted on special terms under the sanction of the Chief Commissioner of British Burmah.

SOLE AGENTS FOR

Robey & Co.'s celebrated Portable and Fixed Engines and Machinery, Gwynne & Co.'s Centrifugal Pumps, Gould's Rotary Pumps, and Robinson's Patent Steam Traps.

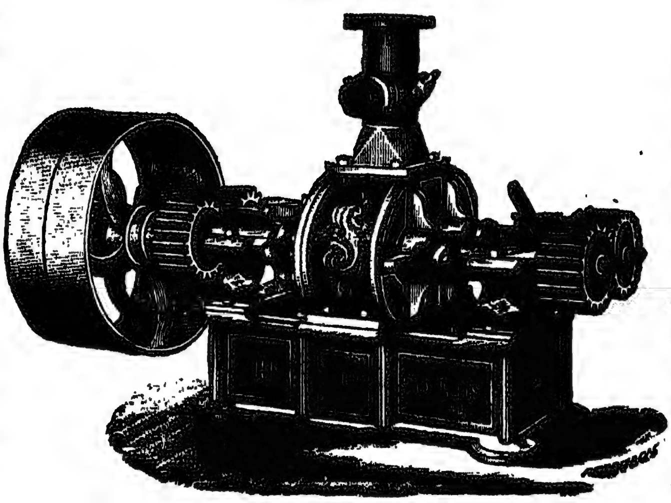
Importers and Manufacturers of every description of Steam Engines and Machinery.

Robey & Co.'s Portable, Horizontal Fixed, and Patent "Robey" Semi-fixed Engines, Combined Vertical Engines and Boilers, Land and Marine Boilers, Gould's Rotary Power Pumps, Hand Lift and Force Pumps, Gwynne's Centrifugal Pumps, Tangye's "Special" Steam Pump, "Vauxhall" Donkey Pumps, Flour Mills, Soorkee Mills, Pug Mills, Brick-making Machines, Road Rollers, Saw Benches, Stoney's Patent Soorkee Screwing Machines and Double Acting Helical Excavators, Slide Surfacing and Screw Cutting Lathes, Drilling Machines, Punching and Shearing, Slotting and Screwing Machines, Emery Grinding Machines, Spencer's Hand Drilling Machines, Chaff Cutting Machines, Kennedy's Patent Bar Shears, Selkirk's Boiler Tube Beaders, Steam Pressure Recorders, Electric Pens, Richard's Engine Indicators, Gifford's Injectors, Cooking Stoves, Fire Proof Safes.

No. 3 Pump, has a 3 inch suction pipe, throws a 2½-inch stream, and with 175 revolutions discharges 175 gallons per minute.

No. 4 Pump, has a 5-inch suction pipe, throws a 4-inch stream, and with 200 revolutions discharges 325 gallons per minute.

No. 5 Pump, has a 6-inch suction pipe, throws a 5-inch stream, and with 200 revolutions discharges 500 gallons per minute.



The mandrels of these Pumps are made of cast-steel with Babbet's metal boxes, and there are no valves or leather packing, which renders them very durable and not likely to get out of order. The great advantage of these over the ordinary Centrifugal Pumps is that they will draw water running at any rate of speed, but of course the higher the speed at which they are driven the greater the discharge obtained.

GOULD'S ROTARY PUMP.

INDIGO AND TEA PLANTERS' IMPLEMENTS AND STORES.

Indigo Screws, Indigo Beaters, Indigo Pans, Indigo Pumps, Howard's Patent D and Turnwrest Ploughs, Kodallies, Pruning and Budding Knives, Grubbing Hoes, Assam Daws and Forks, Bill Hooks, American Felling Axes, Scissors, Shears, Saws, Mowing Machines, Tea Sieves, Tea Lead Solder, Galvanized Netting, Iron and Brass Wire Gauze, Leather and India-rubber Belting, Tool Chests, Grindstones, India-rubber Suction and Delivery Hose, Canvas Hose, French Wire and other Nails, Hoop Iron, Platform Weighing Machines, Spring Balances, Gram and Oat Crushing Machines, Maximum and Minimum Thermometers, Steel Band Chains for land measuring.

BIRD & CO.,

MANUFACTURERS OF THE

PATENT IMPROVED LEATHER—

OIL-PROOF, WATER-PROOF, IMPERISHABLE.

WORKS:—

LIME-HOUSE, LONDON, E.

THIS Leather is submitted to a patent process, rendering it stronger, more durable, and impervious to damp and heat. Being water-proof, it is particularly adapted to work in wet and exposed situations, and in the hot and moist atmosphere of the Tropics.

THE BANDS

Will stretch less than those made of ordinary leather, thus saving both the time and trouble so frequently expended in taking up belting; while for agricultural purposes, where the Bands have to remain in the open, this Leather will be found invaluable.

THE HOSE PIPING.

Besides being stronger than ordinary hose, never becomes hard, requires no oiling or dressing, and after being used, can be put away until next wanted without any further care or labour being bestowed upon it.

THE BUCKETS

Are handsomer, stronger, and lighter, and will last longer than those made of wood or iron.

THE HARNESS

Will bear exposure to the heaviest rain, only requires to be wiped with a dry cloth; neither oiling nor dressing is wanted. The leather, which is particularly recommended for Cart and Heavy Harness, though equally valuable for lighter purposes, such as Carriage Hoods, Aprons, &c.

BOOT AND SHOE PURPOSES.

The Soles and Clumps are perfectly impervious to rain and snow water, and keep the feet warm and dry in the coldest or wettest weather. Uppers can also be made waterproof.

ARMY PURPOSES.

This Patent Leather will be found most valuable and economical in the various departments of the Army, retaining its specific properties until worn out, and requiring but little care and attention; the saving in time and money, in Artillery harness alone will be great. This Leather will be found particularly adapted for use in India and all tropical climates, where the great heat and moisture prove so destructive to ordinary Leather.

GENERAL PURPOSES.

There are of course numberless other purposes to which this Leather can be applied, at, *viz* :—Pump Leathers, Portmanteaus, Bags, Gun Cases, Cartridge Boxes, Belts, Straps, &c., &c., and any information required can be obtained on application at the Works, Limehouse, London, E.

EDUCATIONAL.

EDUCATION

WITH SIGNAL ADVANTAGES.

IN THE HEALTHIEST LOCALITY OF THE HEALTHIEST PART OF THE EARTH

LIEUTENANT-COLONEL E F ANGELO, an ex-Staff Officer of the Royal Army in India, who recently retired to settle in Tasmania, has selected as his permanent abode the town of FORMBY at the mouth of the *Mersey* river, and has made arrangements for the education of his own sons and those of gentlemen in the neighbourhood, and these arrangements are such as to enable him to extend the advantages thus secured to the sons of gentlemen in India

The sons of Officers and Civilians in India will be received into Colonel Angelo's own family, and will prosecute a course of study which will comprise all the branches included in the curriculum of a first-class academy.

TERMS:

Boys under 12 years of age.

Resident boarders ... . £50 per annum

Boys above 12 years of age.

Resident boarders ... £60 per annum.

No extra charges except for Music and Drawing. The course of instruction will include military drill and gymnastics.

Parents accompanying their children from India, can have accommodation secured for them at some of the neighbouring boarding-houses, the average charge being 30*s*. a week.

Address, for any further information, Dr. A G Fraser, Magistrate, F.C, Poonah, Bombay Presidency, or Leith Fraser, Esq., B C S, Assistant Secretary to Chief Commissioner, Central Provinces, Nagpore, or Lieutenant-Colonel Angelo, Stone-house, Formby, on the Mersey, Tasmania

P.S.—A peculiar advantage is offered to those families in India, who have it in view to settle in Tasmania at the termination of their Indian career. Any family by leaving one of its members for five years in the Colony, establishes a title to a free grant of the land to which such family may be entitled as immigrants under the Waste Land Act that is to say, any Officer or Civilian in India, proposing to settle in Tasmania on his retirement from the public service, must reside five years in the Colony before his grant of land is made over to him in fee-simple, but he can claim possession, immediately on his retirement, of his goodly inheritance there by sending a son to the Colony five years before he can claim to retire here.

A LADY and Gentleman residing near London, are willing to undertake the charge of two or three young children. Every care would be taken, a superior education imparted, and the comforts of a happy Christian home provided.

The highest references will be furnished.

Applications for further particulars and terms should be addressed South Norwood, care of D. J. Keymer & Co., 1, Whitefriar's-street, London, E. C.
